## Features

- 80C51 Core Architecture
- 256 Bytes of On-chip RAM
- 1 KB of On-chip XRAM
- 32 KB of On-chip Flash Memory
- Data Retention: 10 Years at $85^{\circ} \mathrm{C}$ Read/Write Cycle: 10K
- 2 KB of On-chip Flash for Bootloader
- 2 KB of On-chip EEPROM

Read/Write Cycle: 100K

- 14-sources 4-level Interrupts
- Three 16-bit Timers/Counters
- Full Duplex UART Compatible 80C51
- Maximum Crystal Frequency 40 MHz, in X2 Mode, 20 MHz (CPU Core, 20 MHz)
- Five Ports: 32 + 2 Digital I/O Lines
- Five-channel 16-bit PCA with:
- PWM (8-bit)
- High-speed Output
- Timer and Edge Capture
- Double Data Pointer
- 21-bit Watchdog Timer (7 Programmable Bits)
- 10-bit Resolution Analog to Digital Converter (ADC) with 8 Multiplexed Inputs
- On-chip Emulation Logic (Enhanced Hook System)
- Power Saving Modes:

## - Idle Mode

- Power-down Mode
- Power Supply: 3V to 5.5V
- Temperature Range: Industrial ( $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$ )
- Packages: VQFP44, PLCC44

## Description

The A/T89C51AC2 is a high performance Flash version of the 80C51 single chip 8-bit microcontrollers. It contains a 32 KB Flash memory block for program and data.
The 32 KB Flash memory can be programmed either in parallel mode or in serial mode with the ISP capability or with software. The programming voltage is internally generated from the standard VCC pin.
The A/T89C51AC2 retains all features of the 80C51 with 256 bytes of internal RAM, a 7 -source 4 -level interrupt controller and three timer/counters. In addition, the A/T89C51AC2 has a 10-bit A/D converter, a 2 KB Boot Flash memory, 2 KB EEPROM for data, a Programmable Counter Array, an XRAM of 1024 bytes, a Hardware WatchDog Timer, and a more versatile serial channel that facilitates multiprocessor communication (EUART). The fully static design of the A/T89C51AC2 reduces system power consumption by bringing the clock frequency down to any value, even DC, without loss of data.
The A/T89C51AC2 has two software-selectable modes of reduced activity and an 8bit clock prescaler for further reduction in power consumption. In the idle mode the CPU is frozen while the peripherals and the interrupt system are still operating. In the Power-down mode the RAM is saved and all other functions are inoperative.
The added features of the A/T89C51AC2 make it more powerful for applications that need A/D conversion, pulse width modulation, high speed I/O and counting capabilities such as industrial control, consumer goods, alarms, motor control, among others. While remaining fully compatible with the 80C52, the T8C51AC2 offers a superset of this standard microcontroller. In X2 mode, a maximum external clock rate of 20 MHz reaches a 300 ns cycle time.

## Block Diagram

## Pin Configuration

Table 1. Pin Description

| Pin Name | Type | Description |
| :---: | :---: | :---: |
| VSS | GND | Circuit ground |
| VCC |  | Supply Voltage |
| VAREF |  | Reference Voltage for ADC |
| VAGND |  | Reference Ground for ADC |
| P0.0:7 | I/O | Port 0: <br> Is an 8 -bit open drain bi-directional I/O port. Port 0 pins that have 1's written to them float, and in this state can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external Program and Data Memory. In this application it uses strong internal pull-ups when emitting 1's. <br> Port 0 also outputs the code Bytes during program validation. External pull-ups are required during program verification. |
| P1.0:7 | I/O | Port 1: <br> Is an 8-bit bi-directional I/O port with internal pull-ups. Port 1 pins can be used for digital input/output or as analog inputs for the Analog Digital Converter (ADC). Port 1 pins that have 1's written to them are pulled high by the internal pull-up transistors and can be used as inputs in this state. As inputs, Port 1 pins that are being pulled low externally will be the source of current ( $\mathrm{I}_{\mathrm{IL}}$, see section "Electrical Characteristic") because of the internal pull-ups. Port 1 pins are assigned to be used as analog inputs via the ADCCF register (in this case the internal pull-ups are disconnected). <br> As a secondary digital function, port 1 contains the Timer 2 external trigger and clock input; the PCA external clock input and the PCA module I/O. <br> P1.0/AN0/T2 <br> Analog input channel 0, <br> External clock input for Timer/counter2. <br> P1.1/AN1/T2EX <br> Analog input channel 1, <br> Trigger input for Timer/counter2. <br> P1.2/AN2/ECI <br> Analog input channel 2, <br> PCA external clock input. <br> P1.3/AN3/CEX0 <br> Analog input channel 3, <br> PCA module 0 Entry of input/PWM output. <br> P1.4/AN4/CEX1 <br> Analog input channel 4, PCA module 1 Entry of input/PWM output. <br> P1.5/AN5/CEX2 <br> Analog input channel 5, PCA module 2 Entry of input/PWM output. <br> P1.6/AN6/CEX3 <br> Analog input channel 6, PCA module 3 Entry of input/PWM output. <br> P1.7/AN7/CEX4 <br> Analog input channel 7, <br> PCA module 4 Entry ot input/PWM output. <br> Port 1 receives the low-order address byte during EPROM programming and program verification. <br> It can drive CMOS inputs without external pull-ups. |
| P2.0:7 | I/O | Port 2: <br> Is an 8-bit bi-directional I/O port with internal pull-ups. Port 2 pins that have 1's written to them are pulled high by the internal pull-ups and can be used as inputs in this state. As inputs, Port 2 pins that are being pulled low externally will be a source of current ( $\mathrm{I}_{\mathrm{L}}$, see section "Electrical Characteristic") because of the internal pull-ups. Port 2 emits the high-order address byte during accesses to the external Program Memory and during accesses to external Data Memory that uses 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1's. During accesses to external Data Memory that use 8 bit addresses (MOVX @Ri), Port 2 transmits the contents of the P2 special function register. It also receives high-order addresses and control signals during program validation. <br> It can drive CMOS inputs without external pull-ups. |

Table 1. Pin Description (Continued)

| Pin Name | Type | Description |
| :---: | :---: | :---: |
| P3.0:7 | I/O | Port 3: <br> Is an 8-bit bi-directional I/O port with internal pull-ups. Port 3 pins that have 1 's written to them are pulled high by the internal pull-up transistors and can be used as inputs in this state. As inputs, Port 3 pins that are being pulled low externally will be a source of current ( $\mathrm{I}_{\mathrm{LL}}$, see section "Electrical Characteristic") because of the internal pull-ups. <br> The output latch corresponding to a secondary function must be programmed to one for that function to operate (except for TXD and $\overline{W R})$. The secondary functions are assigned to the pins of port 3 as follows: <br> P3.0/RxD: <br> Receiver data input (asynchronous) or data input/output (synchronous) of the serial interface <br> P3.1/TxD: <br> Transmitter data output (asynchronous) or clock output (synchronous) of the serial interface <br> P3.2/INT0: <br> External interrupt 0 input/timer 0 gate control input <br> P3.3/INT1: <br> External interrupt 1 input/timer 1 gate control input <br> P3.4/T0: <br> Timer 0 counter input <br> P3.5/T1: <br> Timer 1 counter input <br> P3.6/WR: <br> External Data Memory write strobe; latches the data byte from port 0 into the external data memory P3.7/RD: <br> External Data Memory read strobe; Enables the external data memory. <br> It can drive CMOS inputs without external pull-ups. |
| P4.0:1 | I/O | Port 4: <br> Is an 2-bit bi-directional I/O port with internal pull-ups. Port 4 pins that have 1's written to them are pulled high by the internal pull-ups and can be used as inputs in this state. As inputs, Port 4 pins that are being pulled low externally will be a source of current (IIL, on the datasheet) because of the internal pull-up transistor. P4.0 <br> P4.1: <br> It can drive CMOS inputs without external pull-ups. |
| RESET | I/O | Reset: <br> A high level on this pin during two machine cycles while the oscillator is running resets the device. An internal pull-down resistor to VSS permits power-on reset using only an external capacitor to VCC. |
| ALE | 0 | ALE: <br> An Address Latch Enable output for latching the low byte of the address during accesses to the external memory. The ALE is activated every $1 / 6$ oscillator periods ( $1 / 3$ in X2 mode) except during an external data memory access. When instructions are executed from an internal Flash ( $\overline{E A}=1$ ), ALE generation can be disabled by the software. |
| PSEN | 0 | $\overline{\text { PSEN: }}$ <br> The Program Store Enable output is a control signal that enables the external program memory of the bus during external fetch operations. It is activated twice each machine cycle during fetches from the external program memory. However, when executing from of the external program memory two activations of PSEN are skipped during each access to the external Data memory. The PSEN is not activated for internal fetches. |
| EA | I | $\overline{E A}$ : <br> When External Access is held at the high level, instructions are fetched from the internal Flash when the program counter is less then 8000 H . When held at the low level,A/T89C51AC2 fetches all instructions from the external program memory. |
| XTAL1 | I | XTAL1: <br> Input of the inverting oscillator amplifier and input of the internal clock generator circuits. To drive the device from an external clock source, XTAL1 should be driven, while XTAL2 is left unconnected. To operate above a frequency of 16 MHz , a duty cycle of $50 \%$ should be maintained. |
| XTAL2 | 0 | XTAL2: <br> Output from the inverting oscillator amplifier. |

## I/O Configurations

Each Port SFR operates via type-D latches, as illustrated in Figure 1 for Ports 3 and 4. A CPU "write to latch" signal initiates transfer of internal bus data into the type-D latch. A CPU "read latch" signal transfers the latched Q output onto the internal bus. Similarly, a "read pin" signal transfers the logical level of the Port pin. Some Port data instructions activate the "read latch" signal while others activate the "read pin" signal. Latch instructions are referred to as Read-Modify-Write instructions. Each I/O line may be independently programmed as input or output.

## Port 1, Port 3 and Port 4

Figure 1 shows the structure of Ports 1 and 3, which have internal pull-ups. An external source can pull the pin low. Each Port pin can be configured either for general-purpose l/O or for its alternate input output function.

To use a pin for general-purpose output, set or clear the corresponding bit in the Px register ( $x=1,3$ or 4 ). To use a pin for general-purpose input, set the bit in the Px register. This turns off the output FET drive.

To configure a pin for its alternate function, set the bit in the Px register. When the latch is set, the "alternate output function" signal controls the output level (see Figure 1). The operation of Ports 1, 3 and 4 is discussed further in the "quasi-Bidirectional Port Operation" section.

Figure 1. Port 1, Port 3 and Port 4 Structure

Note: $\quad$ The internal pull-up can be disabled on P1 when analog function is selected.

## Port 0 and Port 2

Ports 0 and 2 are used for general-purpose I/O or as the external address/data bus. Port 0 , shown in Figure 3, differs from the other Ports in not having internal pull-ups. Figure 3 shows the structure of Port 2. An external source can pull a Port 2 pin low.

To use a pin for general-purpose output, set or clear the corresponding bit in the Px register ( $\mathrm{x}=0$ or 2). To use a pin for general-purpose input, set the bit in the Px register to turn off the output driver FET.

Figure 2. Port 0 Structure

Notes: 1. Port 0 is precluded from use as general-purpose $I / O$ Ports when used as address/data bus drivers.
2. Port 0 internal strong pull-ups assist the logic-one output for memory bus cycles only. Except for these bus cycles, the pull-up FET is off, Port 0 outputs are open-drain.

Figure 3. Port 2 Structure

Notes: 1. Port 2 is precluded from use as general-purpose I/O Ports when as address/data bus drivers.
2. Port 2 internal strong pull-ups FET (P1 in FiGURE) assist the logic-one output for memory bus cycle.
When Port 0 and Port 2 are used for an external memory cycle, an internal control signal switches the output-driver input from the latch output to the internal address/data line.

## Read-Modify-Write Instructions

Some instructions read the latch data rather than the pin data. The latch based instructions read the data, modify the data and then rewrite the latch. These are called "Read-Modify-Write" instructions. Below is a complete list of these special instructions (see Table ). When the destination operand is a Port or a Port bit, these instructions read the latch rather than the pin:

Table 2. Read-Modify-Write Instructions

| Instruction | Description | Example |
| :---: | :--- | :--- |
| ANL | logical AND | ANL P1, A |
| ORL | logical OR | ORL P2, A |
| XRL | logical EX-OR | XRL P3, A |
| JBC | jump if bit = 1 and clear bit | CPL P3.0 |
| CPL | complement bit | INC P2 |
| INC | increment | DEC P2 |
| DEC | decrement | DJNZ P3, LABEL |
| DJNZ | decrement and jump if not zero |  |
| MOV Px.y, C | move carry bit to bit y of Port x | MOV P1.5, C |
| CLR Px.y | clear bit y of Port $x$ | CLR P2.4 |
| SET Px.y | set bit y of Port x | SET P3.3 |

It is not obvious the last three instructions in this list are Read-Modify-Write instructions. These instructions read the port (all 8 bits), modify the specifically addressed bit and write the new byte back to the latch. These Read-Modify-Write instructions are directed to the latch rather than the pin in order to avoid possible misinterpretation of voltage (and therefore, logic) levels at the pin. For example, a Port bit used to drive the base of an external bipolar transistor can not rise above the transistor's base-emitter junction voltage (a value lower than VIL). With a logic one written to the bit, attempts by the CPU to read the Port at the pin are misinterpreted as logic zero. A read of the latch rather than the pins returns the correct logic-one value.

## Quasi-Bidirectional Port Operation

Port 1, Port 2, Port 3 and Port 4 have fixed internal pull-ups and are referred to as "quasi-bidirectional" Ports. When configured as an input, the pin impedance appears as logic one and sources current in response to an external logic zero condition. Port 0 is a "true bidirectional" pin. The pins float when configured as input. Resets write logic one to all Port latches. If logical zero is subsequently written to a Port latch, it can be returned to input conditions by a logical one written to the latch.
Note: Port latch values change near the end of Read-Modify-Write instruction cycles. Output buffers (and therefore the pin state) update early in the instruction after Read-ModifyWrite instruction cycle.

Logical zero-to-one transitions in Port 1, Port 2, Port 3 and Port 4 use an additional pullup (p1) to aid this logic transition (see Figure 4.). This increases switch speed. This extra pull-up sources 100 times normal internal circuit current during 2 oscillator clock periods. The internal pull-ups are field-effect transistors rather than linear resistors. Pullups consist of three p-channel FET (pFET) devices. A pFET is on when the gate senses logical zero and off when the gate senses logical one. PFET \#1 is turned on for two oscillator periods immediately after a zero-to-one transition in the Port latch. A logical one at the Port pin turns on PFET \#3 (a weak pull-up) through the inverter. This inverter and pFET pair form a latch to drive logical one. pFET \#2 is a very weak pull-up switched on whenever the associated nFET is switched off. This is traditional CMOS switch convention. Current strengths are $1 / 10$ that of pFET \#3.

Figure 4. Internal Pull-Up Configurations

Note: Port 2 p 1 assists the logic-one output for memory bus cycles.

SFR Mapping
The Special Function Registers (SFRs) of the A/T89C51AC2 fall into the following categories:

Table 3. C51 Core SFRs

| Mnemonic | Add | Name | $\mathbf{7}$ | $\mathbf{6}$ | $\mathbf{5}$ | $\mathbf{4}$ | $\mathbf{3}$ | $\mathbf{2}$ | $\mathbf{1}$ | $\mathbf{0}$ |

## Reserved

Note: 1. These registers are bit-addressable.
Sixteen addresses in the SFR space are both byte-addressable and bit-addressable. The bit-addressable SFR's are those whose address ends in 0 and 8 . The bit addresses, in this area, are $0 \times 80$ through to 0xFF.

## Clock

## Description

The A/T89C51AC2 core needs only 6 clock periods per machine cycle. This feature, called "X2", provides the following advantages:

- Divides frequency crystals by 2 (cheaper crystals) while keeping the same CPU power.
- Saves power consumption while keeping the same CPU power (oscillator power saving).
- Saves power consumption by dividing dynamic operating frequency by 2 in operating and idle modes.
- Increases CPU power by 2 while keeping the same crystal frequency.

In order to keep the original C51 compatibility, a divider-by-2 is inserted between the XTAL1 signal and the main clock input of the core (phase generator). This divider may be disabled by the software.
An extra feature is available to start after Reset in the X2 mode. This feature can be enabled by a bit X2B in the Hardware Security Byte. This bit is described in the section "In-System-Programming".

The X2 bit in the CKCON register (see Table 12) allows switching from 12 clock cycles per instruction to 6 clock cycles and vice versa. At reset, the standard speed is activated (STD mode).
Setting this bit activates the X2 feature (X2 mode) for the CPU Clock only (see Figure 5.).

The Timers 0, 1 and 2, Uart, PCA, or Watchdog switch in X2 mode only if the corresponding bit is cleared in the CKCON register.
The clock for the whole circuit and peripheral is first divided by two before being used by the CPU core and peripherals. This allows any cyclic ratio to be accepted on the XTAL1 input. In X2 mode, as this divider is bypassed, the signals on XTAL1 must have a cyclic ratio between 40 to $60 \%$. Figure 5. shows the clock generation block diagram. The X2 bit is validated on the XTAL1 $\div 2$ rising edge to avoid glitches when switching from the X2 to the STD mode. Figure 6 shows the mode switching waveforms.

Figure 5. Clock CPU Generation Diagram

Figure 6. Mode Switching Waveforms

Note: In order to prevent any incorrect operation while operating in the X2 mode, users must be aware that all peripherals using the clock frequency as a time reference (UART, timers...) will have their time reference divided by two. For example a free running timer generating an interrupt every 20 ms will then generate an interrupt every 10 ms . A UART with a 4800 baud rate will have a 9600 baud rate.

| 0 | X2 | CPU clock <br> Clear to select 12 clock periods per machine cycle (STD mode) for CPU and all the peripherals. <br> Set to select 6 clock periods per machine cycle (X2 mode) and to enable the individual peripherals "X2"bits. |

Note: 1. This control bit is validated when the CPU clock bit X 2 is set; when X 2 is low, this bit has no effect.
Reset Value $=x 0000000 \mathrm{~b}$

Power Management

Reset Pin
Two power reduction modes are implemented in the A/T89C51AC2: the Idle mode and the Power-down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 Mode detailed in Section "Clock".

In order to start-up (cold reset) or to restart (warm reset) properly the microcontroller, a high level has to be applied on the RST pin. A bad level leads to a wrong initialisation of the internal registers like SFRs, PC, etc. and to unpredictable behavior of the microcontroller. A warm reset can be applied either directly on the RST pin or indirectly by an internal reset source such as a watchdog, PCA, timer, etc.

## At Power-up (Cold Reset)

Two conditions are required before enabling a CPU start-up:

- VDD must reach the specified VDD range,
- The level on xtal1 input must be outside the specification (VIH, VIL).

If one of these two conditions are not met, the microcontroller does not start correctly and can execute an instruction fetch from anywhere in the program space. An active level applied on the RST pin must be maintained until both of the above conditions are met. A reset is active when the level VIH1 is reached and when the pulse width covers the period of time where VDD and the oscillator are not stabilized. Two parameters have to be taken into account to determine the reset pulse width:

- VDD rise time (vddrst),
- Oscillator startup time (oscrst).

To determine the capacitor the highest value of these two parameters has to be chosen. The reset circuitry is shown in Figure 7.

Figure 7. Reset Circuitry

0

Table 13 and Table 15 give some typical examples for three values of VDD rise times, two values of oscillator start-up time and two pull-down resistor values.

Table 13. Minimum Reset Capacitor for a 15k Pull-down Resistor

| oscrst/vddrst | 1 ms | 10 ms | 100 ms |
| :---: | :---: | :---: | :---: |
| 5 ms | $2.7 \mu \mathrm{~F}$ | $4.7 \mu \mathrm{~F}$ | $47 \mu \mathrm{~F}$ |
| 20 ms | $10 \mu \mathrm{~F}$ | $15 \mu \mathrm{~F}$ | $47 \mu \mathrm{~F}$ |

Note: These values assume VDD starts from $0 v$ to the nominal value. If the time between two on/off sequences is too fast, the power-supply de coupling capacitors may not be fully discharged, leading to a bad reset sequence.

## Warm Reset

## Watchdog Reset

To achieve a valid reset, the reset signal must be maintained for at least 2 machine cycles ( 24 oscillator clock periods) while the oscillator is running. The number of clock periods is mode independent (X2 or X1).

As detailed in Section "PCA Watchdog Timer", page 80, the WDT generates a 96-clock period pulse on the RST pin. In order to properly propagate this pulse to the rest of the application in case of external capacitor or power-supply supervisor circuit, a $1 \mathrm{~K} \Omega$ resistor must be added as shown Figure 8.

Figure 8. Reset Circuitry for WDT reset out usage

## Idle Mode

## | Entering Idle Mode

## Exiting Idle Mode

An example of bad initialization situation may occur in an instance where the bit ENBOOT in AUXR1 register is initialized from the hardware bit BLJB upon reset. Since this bit allows mapping of the bootloader in the code area, a reset failure can be critical.
If one wants the ENBOOT cleared in order to unmap the boot from the code area (yet due to a bad reset) the bit ENBOOT in SFRs may be set. If the value of Program Counter is accidently in the range of the boot memory addresses then a flash access (write or erase) may corrupt the Flash on-chip memory.

It is recommended to use an external reset circuitry featuring power supply monitoring to prevent system malfunction during periods of insufficient power supply voltage (power supply failure, power supply switched off).

Idle mode is a power reduction mode that reduces the power consumption. In this mode, program execution halts. Idle mode freezes the clock to the CPU at known states while the peripherals continue to be clocked. The CPU status before entering Idle mode is preserved, i.e., the program counter and program status word register retain their data for the duration of Idle mode. The contents of the SFRs and RAM are also retained. The status of the Port pins during Idle mode is detailed in Table 14.

To enter Idle mode, you must set the IDL bit in PCON register (see Table 15). The T89C51CC02 enters Idle mode upon execution of the instruction that sets IDL bit. The instruction that sets IDL bit is the last instruction executed.
Note: If IDL bit and PD bit are set simultaneously, the T89C51CC02 enters Power-down mode. Then it does not go in Idle mode when exiting Power-down mode.

There are two ways to exit Idle mode:

1. Generate an enabled interrupt.

- Hardware clears IDL bit in PCON register which restores the clock to the CPU. Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Idle mode.

The general-purpose flags (GF1 and GF0 in PCON register) may be used to indicate whether an interrupt occurred during normal operation or during Idle mode. When Idle mode is exited by an interrupt, the interrupt service routine may examine GF1 and GF0.
2. Generate a reset.

- A logic high on the RST pin clears IDL bit in PCON register directly and asynchronously. This restores the clock to the CPU. Program execution momentarily resumes with the instruction immediately following the instruction that activated the Idle mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the T89C51CC02 and vectors the CPU to address C:0000h.

Notes: 1. During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated Idle mode should not write to a Port pin or to the external RAM.
2. If Idle mode is invoked by ADC Idle, the ADC conversion completion will exit Idle.

## Power-down Mode

Entering Power-down Mode

## Exiting Power-down Mode

The Power-down mode places the T89C51CC02 in a very low power state. Power-down mode stops the oscillator and freezes all clocks at known states. The CPU status prior to entering Power-down mode is preserved, i.e., the program counter, program status word register retain their data for the duration of Power-down mode. In addition, the SFRs and RAM contents are preserved. The status of the Port pins during Power-down mode is detailed in Table 14.

To enter Power-down mode, set PD bit in PCON register. The T89C51CC02 enters the Power-down mode upon execution of the instruction that sets PD bit. The instruction that sets PD bit is the last instruction executed.

If VDD was reduced during the Power-down mode, do not exit Power-down mode until VDD is restored to the normal operating level.

There are two ways to exit the Power-down mode:

1. Generate an enabled external interrupt.

- The T89C51CC02 provides capability to exit from Power-down using INT0\#, INT1\#.
Hardware clears PD bit in PCON register which starts the oscillator and restores the clocks to the CPU and peripherals. Using INTX\# input, execution resumes when the input is released (see Figure 9) while using KINx input, execution resumes after counting 1024 clock ensuring the oscillator is restarted properly (see Figure 8). Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Power-down mode.

Note: 1. The external interrupt used to exit Power-down mode must be configured as level sensitive (INT0\# and INT1\#) and must be assigned the highest priority. In addition, the duration of the interrupt must be long enough to allow the oscillator to stabilize. The execution will only resume when the interrupt is deasserted.
2. Exit from power-down by external interrupt does not affect the SFRs nor the internal RAM content.

Figure 9. Power-down Exit Waveform Using INT1:0\#

2. Generate a reset.

- A logic high on the RST pin clears PD bit in PCON register directly and asynchronously. This starts the oscillator and restores the clock to the CPU and peripherals. Program execution momentarily resumes with the instruction immediately following the instruction that activated Power-down mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the T89C51CC02 and vectors the CPU to address 0000 h .
Notes: 1. During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated the Power-down mode should not write to a Port pin or to the external RAM.

2. Exit from power-down by reset redefines all the SFRs, but does not affect the internal RAM content.

Table 14. Pin Conditions in Special Operating Modes

| Mode | Port 0 | Port 1 | Port 2 | Port 3 | Port 4 | ALE | PSEN\# |

## Data Memory

The A/T89C51AC2 provides data memory access in two different spaces:

1. The internal space mapped in three separate segments:

- the lower 128 Bytes RAM segment.
- the upper 128 Bytes RAM segment.
- the expanded 1024 Bytes RAM segment (XRAM).

2. The external space.

A fourth internal segment is available but dedicated to Special Function Registers, SFRs, (addresses 80h to FFh) accessible by direct addressing mode.
Figure 11 shows the internal and external data memory spaces organization.
Figure 10. Internal Memory - RAM

Figure 11. Internal and External Data Memory Organization XRAM-XRAM

## Internal Space

Lower 128 Bytes RAM

Upper 128 Bytes RAM

Expanded RAM

The lower 128 Bytes of RAM (see Figure 11) are accessible from address 00h to 7Fh using direct or indirect addressing modes. The lowest 32 Bytes are grouped into 4 banks of 8 registers (R0 to R7). Two bits RS0 and RS1 in PSW register (see Figure 18) select which bank is in use according to Table 16. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing, and can be used for context switching in interrupt service routines.

Table 16. Register Bank Selection

| RS1 | RS0 | Description |
| :---: | :---: | :--- |
| 0 | 0 | Register bank 0 from 00h to 07h |
| 0 | 1 | Register bank 0 from 08h to 0Fh |
| 1 | 0 | Register bank 0 from 10h to 17h |
| 1 | 1 | Register bank 0 from 18h to 1Fh |

The next 16 Bytes above the register banks form a block of bit-addressable memory space. The C51 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00 h to 7 Fh .

Figure 12. Lower 128 Bytes Internal RAM Organization

The upper 128 Bytes of RAM are accessible from address $80 h$ to FFh using only indirect addressing mode.

The on-chip 1024 Bytes of expanded RAM (XRAM) are accessible from address 0000h to 03FFh using indirect addressing mode through MOVX instructions. In this address range, the bit EXTRAM in AUXR register is used to select the XRAM (default) or the XRAM. As shown in Figure 11 when EXTRAM $=0$, the XRAM is selected and when EXTRAM $=1$, the XRAM is selected.

The size of XRAM can be configured by XRS1-0 bit in AUXR register (default size is 1024 Bytes).
Note: Lower 128 Bytes RAM, Upper 128 Bytes RAM, and expanded RAM are made of volatile memory cells. This means that the RAM content is indeterminate after power-up and must then be initialized properly.

## External Space

## Memory Interface

## External Bus Cycles

The external memory interface comprises the external bus (port 0 and port 2 ) as well as the bus control signals ( $\overline{\mathrm{RD}}, \overline{\mathrm{WR}}$, and ALE).

Figure 13 shows the structure of the external address bus. P0 carries address A7:0 while P2 carries address A15:8. Data D7:0 is multiplexed with A7:0 on P0. Table 17 describes the external memory interface signals.

Figure 13. External Data Memory Interface Structure

Table 17. External Data Memory Interface Signals

| Signal <br> Name | Type | Description | Alternative <br> Function |
| :---: | :---: | :--- | :---: |
| A15:8 | O | Address Lines <br> Upper address lines for the external bus. | $\mathrm{P} 2.7: 0$ |
| AD7:0 | $1 / \mathrm{O}$ | Address/Data Lines <br> Multiplexed lower address lines and data for the external <br> memory. | $\mathrm{P} 0.7: 0$ |
| ALE | O | Address Latch Enable <br> ALE signals indicates that valid address information are available <br> on lines AD7:0. | - |
| $\overline{\mathrm{RD}}$ | O | Read <br> Read signal output to external data memory. | P 3.7 |
| $\overline{\mathrm{WR}}$ | O | Write <br> Write signal output to external memory. | P 3.6 |

This section describes the bus cycles the A/T89C51AC2 executes to read (see Figure 14), and write data (see Figure 15) in the external data memory.
External memory cycle takes 6 CPU clock periods. This is equivalent to 12 oscillator clock period in standard mode or 6 oscillator clock periods in X2 mode. For further information on X2 mode.

Slow peripherals can be accessed by stretching the read and write cycles. This is done using the MO bit in AUXR register. Setting this bit changes the width of the $\overline{\mathrm{RD}}$ and $\overline{\mathrm{WR}}$ signals from 3 to 15 CPU clock periods.

For simplicity, the accompanying figures depict the bus cycle waveforms in idealized form and do not provide precise timing information. For bus cycle timing parameters refer to the Section "AC Characteristics".

Figure 14. External Data Read Waveforms

Notes: 1. $\overline{R D}$ signal may be stretched using $M 0$ bit in AUXR register.
2. When executing MOVX @Ri instruction, P2 outputs SFR content.

Figure 15. External Data Write Waveforms

Notes: 1. $\overline{\mathrm{WR}}$ signal may be stretched using M0 bit in AUXR register.
2. When executing MOVX @Ri instruction, P2 outputs SFR content.

## Dual Data Pointer

## Description

## Application

The A/T89C51AC2 implements a second data pointer for speeding up code execution and reducing code size in case of intensive usage of external memory accesses. DPTR 0 and DPTR 1 are seen by the CPU as DPTR and are accessed using the SFR addresses 83 h and 84 h that are the DPH and DPL addresses. The DPS bit in AUXR1 register (see Figure 20) is used to select whether DPTR is the data pointer 0 or the data pointer 1 (see Figure 16).

Figure 16. Dual Data Pointer Implementation

Software can take advantage of the additional data pointers to both increase speed and reduce code size, for example, block operations (copy, compare...) are well served by using one data pointer as a "source" pointer and the other one as a "destination" pointer. Hereafter is an example of block move implementation using the two pointers and coded in assembler. The latest C compiler takes also advantage of this feature by providing enhanced algorithm libraries.

The INC instruction is a short (2 Bytes) and fast ( 6 machine cycle) way to manipulate the DPS bit in the AUXR1 register. However, note that the INC instruction does not directly force the DPS bit to a particular state, but simply toggles it. In simple routines, such as the block move example, only the fact that DPS is toggled in the proper sequence matters, not its actual value. In other words, the block move routine works the same whether DPS is ' 0 ' or ' 1 ' on entry.

EEPROM Data
Memory

The 2 KB on-chip EEPROM memory block is located at addresses 0000h to 07FFh of the XRAM/XRAM memory space and is selected by setting control bits in the EECON register. A read in the EEPROM memory is done with a MOVX instruction.

A physical write in the EEPROM memory is done in two steps: write data in the column latches and transfer of all data latches into an EEPROM memory row (programming).

The number of data written on the page may vary from 1 up to 128 Bytes (the page size). When programming, only the data written in the column latch is programmed and a ninth bit is used to obtain this feature. This provides the capability to program the whole memory by Bytes, by page or by a number of Bytes in a page. Indeed, each ninth bit is set when the writing the corresponding byte in a row and all these ninth bits are reset after the writing of the complete EEPROM row.

## Write Data in the Column Latches

Data is written by byte to the column latches as for an external RAM memory. Out of the 11 address bits of the data pointer, the 4 MSBs are used for page selection (row) and 7 are used for byte selection. Between two EEPROM programming sessions, all the addresses in the column latches must stay on the same page, meaning that the 4 MSB must no be changed.

The following procedure is used to write to the column latches:

- Save and disable interrupt.
- Set bit EEE of EECON register
- Load DPTR with the address to write
- Store A register with the data to be written
- Execute a MOVX @DPTR, A
- If needed loop the three last instructions until the end of a 128 Bytes page
- Restore interrupt.

Note: The last page address used when loading the column latch is the one used to select the page programming address.

## Programming

The EEPROM programming consists of the following actions:

- writing one or more Bytes of one page in the column latches. Normally, all Bytes must belong to the same page; if not, the last page address will be latched and the others discarded.
- launching programming by writing the control sequence (50h followed by AOh) to the EECON register.
- EEBUSY flag in EECON is then set by hardware to indicate that programming is in progress and that the EEPROM segment is not available for reading.
- The end of programming is indicated by a hardware clear of the EEBUSY flag.

Note: The sequence $5 \times h$ and Axh must be executed without instructions between then otherwise the programming is aborted.

Read Data
The following procedure is used to read the data stored in the EEPROM memory:

- Save and disable interrupt
- Set bit EEE of EECON register
- Load DPTR with the address to read
- Execute a MOVX A, @DPTR
- Restore interrupt

## Examples

```
;* NAME: api_rd_eeprom_byte
;* DPTR contain address to read.
;* Acc contain the reading value
;* NOTE: before execute this function, be sure the EEPROM is not BUSY

## Program/Code Memory

The A/T89C51AC2 implement 32 KB of on-chip program/code memory. Figure 17 shows the partitioning of internal and external program/code memory spaces depending on the product.
The Flash memory increases EPROM and ROM functionality by in-circuit electrical erasure and programming. Thanks to the internal charge pump, the high voltage needed for programming or erasing Flash cells is generated on-chip using the standard VDD voltage. Thus, the Flash Memory can be programmed using only one voltage and allows In-System-Programming commonly known as ISP. Hardware programming mode is also available using specific programming tool.

Figure 17. Program/Code Memory Organization

Notes: 1. If the program executes exclusively from on-chip code memory (not from external memory), beware of executing code from the upper byte of on-chip memory (7FFFh) and thereby disrupt I/O Ports 0 and 2 due to external prefetch. Fetching code constant from this location does not affect Ports 0 and 2.
2. Default factory programmed parts come with maximum hardware protection. Execution from external memory is not possible unless the Hardware Security Byte is reprogrammed. See Table 26.

## External Code Memory Access

Memory Interface

The external memory interface comprises the external bus (port 0 and port 2 ) as well as the bus control signals (PSEN\#, and ALE).

Figure 18 shows the structure of the external address bus. P0 carries address A7:0 while P2 carries address A15:8. Data D7:0 is multiplexed with A7:0 on P0. Table 18 describes the external memory interface signals.

Figure 18. External Code Memory Interface Structure

Table 22. External Code Memory Interface Signals

| Signal <br> Name | Type | Description | Alternate <br> Function |
| :---: | :---: | :--- | :---: |
| A15:8 | O | Address Lines <br> Upper address lines for the external bus. | P2.7:0 |

| PSEN\# | O | Program Store Enable Output <br> This signal is active low during external code fetch or external code read <br> (MOVC instruction). | - |

## External Bus Cycles

This section describes the bus cycles the A/T89C51AC2 executes to fetch code (see Figure 19) in the external program/code memory.

External memory cycle takes 6 CPU clock periods. This is equivalent to 12 oscillator clock period in standard mode or 6 oscillator clock periods in X2 mode. For further information on X2 mode see section "Clock ".

For simplicity, the accompanying figure depicts the bus cycle waveforms in idealized form and do not provide precise timing information.

For bus cycling parameters refer to the 'AC-DC parameters' section.

Figure 19. External Code Fetch Waveforms

Flash Memory Architecture

A/T89C51AC2 features two on-chip Flash memories:

- Flash memory FMO:
containing 32 KB of program memory (user space) organized into 128 byte pages,
- Flash memory FM1:

2 KB for boot loader and Application Programming Interfaces (API).
The FMO can be program by both parallel programming and Serial In-System-Programming (ISP) whereas FM1 supports only parallel programming by programmers. The ISP mode is detailed in the "In-System-Programming" section.
All Read/Write access operations on Flash Memory by user application are managed by a set of API described in the "In-System-Programming" section.

Figure 20. Flash Memory Architecture

FMO Memory Architecture

User Space

Extra Row (XRow)

Hardware Security Byte

Column Latches

The Flash memory is made up of 4 blocks (see Figure 20):

- The memory array (user space) 32 KB
- The Extra Row
- The Hardware security bits
- The column latch registers

This space is composed of a 32 KB Flash memory organized in 256 pages of 128 Bytes. It contains the user's application code.

This row is a part of FM0 and has a size of 128 Bytes. The extra row may contain information for boot loader usage.

The Hardware security Byte space is a part of FM0 and has a size of 1 byte. The 4 MSB can be read/written by software, the 4 LSB can only be read by software and written by hardware in parallel mode.

The column latches, also part of FM0, have a size of full page (128 Bytes).
The column latches are the entrance buffers of the three previous memory locations (user array, XROW and Hardware security byte).

The FM0 memory can be program only from FM1. Programming FM0 from FM0 or from external memory is impossible.
The FM1 memory can be program only by parallel programming.
The Table 23 show all software Flash access allowed.

Table 23. Cross Flash Memory Access

|  |  | Action | FMO (user Flash) | FM1 (boot Flash) |

## Overview of FMO <br> Operations

The CPU interfaces to the Flash memory through the FCON register and AUXR1 register.
These registers are used to:

- Map the memory spaces in the adressable space
- Launch the programming of the memory spaces
- Get the status of the Flash memory (busy/not busy)

Mapping of the Memory Space By default, the user space is accessed by MOVC instruction for read only. The column latches space is made accessible by setting the FPS bit in FCON register. Writing is possible from 0000h to 7FFFh, address bits 6 to 0 are used to select an address within a page while bits 14 to 7 are used to select the programming address of the page.
Setting FPS bit takes precedence on the EXTRAM bit in AUXR register.
The other memory spaces (user, extra row, hardware security) are made accessible in the code segment by programming bits FMOD0 and FMOD1 in FCON register in accordance with Table 24. A MOVC instruction is then used for reading these spaces.

Table 24. FMO Blocks Select Bits

| FMOD1 | FMOD0 | FMO Adressable space |
| :---: | :---: | :--- |
| 0 | 0 | User (0000h-7FFFh) |
| 0 | 1 | Extra Row(FF80h-FFFFh) |
| 1 | 0 | Hardware Security Byte (0000h) |
| 1 | 1 | Reserved |

## Launching Programming

FPL3:0 bits in FCON register are used to secure the launch of programming. A specific sequence must be written in these bits to unlock the write protection and to launch the programming. This sequence is $5 x h$ followed by Axh. Table 25 summarizes the memory spaces to program according to FMOD1:0 bits.

Table 25. Programming Spaces

|  | Write to FCON |  |  |  | Operation |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | FPL3:0 | FPS | FMOD1 | FMODO |  |
| User | 5 | X | 0 | 0 | No action |
|  | A | X | 0 | 0 | Write the column latches in user space |
|  | 5 | X | 0 | 1 | No action |
| Extra Row | A | X | 0 | 1 | Write the column latches in extra row space |
| Hardware Security Byte | 5 | X | 1 | 0 | No action |
|  | A | X | 1 | 0 | Write the fuse bits space |
| Reserved | 5 | X | 1 | 1 | No action |
|  | A | X | 1 | 1 | No action |

Notes: 1. The sequence $5 x h$ and Axh must be executing without instructions between them otherwise the programming is aborted.
2. Interrupts that may occur during programming time must be disabled to avoid any spurious exit of the programming mode.

## Status of the Flash Memory

## Selecting FM1

Loading the Column Latches

The bit FBUSY in FCON register is used to indicate the status of programming. FBUSY is set when programming is in progress.

The bit ENBOOT in AUXR1 register is used to map FM1 from F800h to FFFFh.
Any number of data from 1 Byte to 128 Bytes can be loaded in the column latches. This provides the capability to program the whole memory by byte, by page or by any number of Bytes in a page.
When programming is launched, an automatic erase of the locations loaded in the column latches is first performed, then programming is effectively done. Thus no page or block erase is needed and only the loaded data are programmed in the corresponding page.

The following procedure is used to load the column latches and is summarized in Figure 21:

- Save then disable interrupt and map the column latch space by setting FPS bit.
- Load the DPTR with the address to load.
- Load Accumulator register with the data to load.
- Execute the MOVX @DPTR, A instruction.
- If needed loop the three last instructions until the page is completely loaded.
- Unmap the column latch and Restore Interrupt

Figure 21. Column Latches Loading Procedure

Note: The last page address used when loading the column latch is the one used to select the page programming address.

## Programming the Flash Spaces

User

Extra Row

The following procedure is used to program the User space and is summarized in Figure 22:

- Load up to one page of data in the column latches from address 0000h to 7FFFh.
- Save then disable the interrupts.
- Launch the programming by writing the data sequence 50 h followed by A 0 h in FCON register (only from FM1).
The end of the programming indicated by the FBUSY flag cleared.
- Restore the interrupts.

The following procedure is used to program the Extra Row space and is summarized in Figure 22:

- Load data in the column latches from address FF80h to FFFFh.
- Save then disable the interrupts.
- Launch the programming by writing the data sequence 52 h followed by A2h in FCON register. This step of the procedure must be executed from FM1. The end of the programming indicated by the FBUSY flag cleared.
The end of the programming indicated by the FBUSY flag cleared.
- Restore the interrupts.

Figure 22. Flash and Extra Row Programming Procedure

## Hardware Security Byte

The following procedure is used to program the Hardware Security Byte space and is summarized in Figure 23:

- Set FPS and map Hardware byte ( $\mathrm{FCON}=0 \times 0 \mathrm{C}$ )
- Save and disable the interrupts.
- Load DPTR at address 0000h.
- Load Accumulator register with the data to load.
- Execute the MOVX @DPTR, A instruction.
- Launch the programming by writing the data sequence 54 h followed by A4h in FCON register. This step of the procedure must be executed from FM1. The end of the programming indicated by the FBUSY flag cleared. The end of the programming indicated by the FBusy flag cleared.
- Restore the interrupts.

Figure 23. Hardware Programming Procedure

## Reading the Flash Spaces

User

## Extra Row

The following procedure is used to read the User space:

- Read one byte in Accumulator by executing MOVC A,@A+DPTR where A+DPTR is the address of the code byte to read.
Note: FCON is supposed to be reset when not needed.
The following procedure is used to read the Extra Row space and is summarized in Figure 24:
- Map the Extra Row space by writing 02h in FCON register.
- Read one byte in Accumulator by executing MOVC A,@A+DPTR with A = 0 and DPTR = FF80h to FFFFh.
- Clear FCON to unmap the Extra Row.

The following procedure is used to read the Hardware Security space and is summarized in Figure 24:

- Map the Hardware Security space by writing 04h in FCON register.
- Read the byte in Accumulator by executing MOVC A,@A+DPTR with A = 0 and DPTR $=0000 \mathrm{~h}$.
- Clear FCON to unmap the Hardware Security Byte.

Figure 24. Reading Procedure

Note: 1. aa = 10 for the Hardware Security Byte.
Flash Protection from Parallel The three lock bits in Hardware Security Byte (see "In-System-Programming" section) Programming are programmed according to Table 26 provide different level of protection for the onchip code and data located in FM0 and FM1.

The only way to write these bits are the parallel mode. They are set by default to level 4

Table 26. Program Lock bit

| Program Lock Bits |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Security <br> Level | LB0 | LB1 | LB2 | Protection Description | | 1 | $U$ | $U$ | $U$ | No program lock features enabled. MOVC instruction executed from <br> external program memory returns non coded data. |
| :---: | :---: | :---: | :---: | :--- |
| 2 | P | $U$ | $U$ | MOVC instructions executed from external program memory are barred <br> to return code bytes from internal memory, EA is sampled and latched <br> on reset, and further parallel programming of the Flash is disabled. |

## Operation Cross Memory Access

Space addressable in read and write are:

- RAM
- ERAM (Expanded RAM access by movx)
- XRAM (eXternal RAM)
- EEPROM DATA
- FMO (user flash)
- Hardware byte
- XROW
- Boot Flash
- Flash Column latch

The table below provide the different kind of memory which can be accessed from different code location.

Table 27. Cross Memory Access

|  | Action | RAM | XRAM ERAM | Boot FLASH | FMO | $\mathrm{E}^{2}$ Data | Hardware Byte | XROW |

1. For DPTR higher than 007Fh only lowest 7 bits are decoded, thus the behavior is the same as for addresses from 0000h to 007Fh
2. For DPTR higher than 007Fh only lowest 7 bits are decoded, thus the behavior is the same as for addresses from 0000h to 007Fh

## In-System Programming (ISP)

With the implementation of the User Space (FM0) and the Boot Space (FM1) in Flash technology the A/T89C51AC2 allows the system engineer the development of applications with a very high level of flexibility. This flexibility is based on the possibility to alter the customer program at any stages of a product's life:

- Before mounting the chip on the PCB, FM0 Flash can be programmed with the application code. FM1 is always preprogrammed by Atmel with a bootloader (UART bootloader). ${ }^{(1)}$
- Once the chip is mounted on the PCB, it can be programmed by serial mode via the UART.
Note: 1. The user can also program his own bootloader in FM1.
This In-System-Programming (ISP) allows code modification over the total lifetime of the product.

Besides the default Boot loader Atmel provide to the customer also all the needed Appli-cation-Programming-Interfaces (API) which are needed for the ISP. The API are located also in the Boot memory.

This allow the customer to have a full use of the 32 KB user memory.
Flash Programming and Erasure

There are three methods of programming the Flash memory:

- The Atmel bootloader located in FM1 is activated by the application. Low level API routines (located in FM1) will be used to program FM0. The interface used for serial downloading to FMO is the UART. API can be called also by the user's bootloader located in FMO at [SBV]OOh.
- A further method exists in activating the Atmel boot loader by hardware activation. See Section "Hardware Security Byte".
- The FMO can be programmed also by the parallel mode using a programmer.

Figure 25. Flash Memory Mapping

## Boot Process

## Software Boot Process Example

## Hardware Boot Process

Many algorithms can be used for the software boot process. Below are descriptions of the different flags and Bytes.

Boot Loader Jump Bit (BLJB):

- This bit indicates if on RESET the user wants to jump to this application at address @0000h on FM0 or execute the boot loader at address @F800h on FM1.
- BLJB = 0 (i.e. bootloader FM1 executed after a reset) is the default Atmel factory programming.
- To read or modify this bit, the APIs are used.

Boot Vector Address (SBV):

- This byte contains the MSB of the user boot loader address in FMO.
- The default value of SBV is FCh (no user boot loader in FM0).
- To read or modify this byte, the APIs are used.

Extra Byte (EB) and Boot Status Byte (BSB):

- These Bytes are reserved for customer use.
- To read or modify these Bytes, the APIs are used.

At the falling edge of RESET, the bit ENBOOT in AUXR1 register is initialized with the value of Boot Loader Jump Bit (BLJB).

Further at the falling edge of RESET if the following conditions (called Hardware condition) are detected. The FCON register is initialized with the value 00h and the PC is initialized with F800h (FM1 lower byte = Bootloader entry point).
Harware Conditions:

- PSEN low ${ }^{(1)}$
- EA high,
- ALE high (or not connected).

The Hardware condition forces the bootloader to be executed, whatever BLJB value is. Then BLBJ will be checked.

If no hardware condition is detected, the FCON register is initialized with the value FOh. Then BLJB value will be checked.

Conditions are:

- If bit BLJB = 1:

User application in FM0 will be started at @0000h (standard reset).

- If bit BLJB = 0:

Boot loader will be started at @F800h in FM1.

Note: 1. As PSEN is an output port in normal operating mode (running user applications or bootloader applications) after reset it is recommended to release PSEN after the falling edge of Reset is signaled.
The hardware conditions are sampled at reset signal Falling Edge, thus they can be released at any time when reset input is low.
2. To ensure correct microcontroller startup, the PSEN pin should not be tied to ground during power-on.

Figure 26. Hardware Boot Process Algorithm

## Application

 Programming InterfaceSeveral Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made by functions.

All of these APIs are described in detail in the following documents on the Atmel web site.

- Datasheet Bootloader UART A/T89C51AC2

Table 32. XROW Mapping

| Description | Default Value | Address |
| :--- | :--- | :--- |
| Copy of the Manufacturer Code | 58 h | 30 h |

| Bit <br> Number | Bit <br> Mnemonic | Description |  |  |  |  |  |
| 7 | X2B | X2 Bit <br> Set this bit to start in standard mode. Clear this bit to start in X2 mode. |  |  |  |  |  |
| 6 | BLJB | Boot Loader JumpBit <br> - 1: To start the user's application on next RESET (@0000h) located in FM0, <br> - 0: To start the boot loader(@F800h) located in FM1. |  |  |  |  |  |
| 5-3 | - | Reserved <br> The value read from these bits are indeterminate. |  |  |  |  |  |
| 2-0 | LB2:0 | Lock Bits |  |  |  |  |  |

After erasing the chip in parallel mode, the default value is : FFh
The erasing in ISP mode (from bootloader) does not modify this byte.
Notes: 1. Only the 4 MSB bits can be accessed by software.
2. The 4 LSB bits can only be accessed by parallel mode.

## Serial I/O Port

The A/T89C51AC2 I/O serial port is compatible with the I/O serial port in the 80C52.
It provides both synchronous and asynchronous communication modes. It operates as a Universal Asynchronous Receiver and Transmitter (UART) in three full-duplex modes (Modes 1, 2 and 3). Asynchronous transmission and reception can occur simultaneously and at different baud rates

Serial I/O port includes the following enhancements:

- Framing error detection
- Automatic address recognition

Figure 27. Serial I/O Port Block Diagram

Framing Error Detection Framing bit error detection is provided for the three asynchronous modes. To enable the framing bit error detection feature, set SMODO bit in PCON register.

Figure 28. Framing Error Block Diagram

When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two CPUs. If a valid stop bit is not found, the Framing Error bit (FE) in SCON register bit is set.

The software may examine the FE bit after each reception to check for data errors. Once set, only software or a reset clears the FE bit. Subsequently received frames with valid stop bits cannot clear the FE bit. When the FE feature is enabled, RI rises on the stop bit instead of the last data bit (See Figure 29. and Figure 30.).

Figure 29. UART Timing in Mode 1

Figure 30. UART Timing in Modes 2 and 3

RI
SMODO $=$

## Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in the hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address will the receiver set the RI bit in the SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.

If necessary, you can enable the automatic address recognition feature in mode 1. In this configuration, the stop bit takes the place of the ninth data bit. Bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.
Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i.e. setting SM2 bit in SCON register in mode 0 has no effect).

## Given Address

## Broadcast Address

Each device has an individual address that is specified in the SADDR register; the SADEN register is a mask byte that contains don't-care bits (defined by zeros) to form the device's given address. The don't-care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed. To address a device by its individual address, the SADEN mask byte must be 1111 1111b.
For example:
SADDR0101 0110b
SADEN1111 1100b
Given0101 01XXb
Here is an example of how to use given addresses to address different slaves:

```
Slave A:SADDR1111 0001b
    SADEN1111 1010b
    Given1111 0x0Xb
Slave B:SADDR1111 0011b
    SADEN1111 1001b
    Given1111 0xX1b
Slave C:SADDR1111 0011b
    SADEN1111 1101b
    Given1111 00X1b
```

The SADEN byte is selected so that each slave may be addressed separately.
For slave A , bit 0 (the LSB) is a don't-care bit; for slaves B and C , bit 0 is a 1 . To communicate with slave A only, the master must send an address where bit 0 is clear (e.g. 11110000 b ).
For slave $A$, bit 1 is a 0 ; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves $A$ and $B$, but not slave $C$, the master must send an address with bits 0 and 1 both set (e.g. 11110011 b).
To communicate with slaves $\mathrm{A}, \mathrm{B}$ and C , the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e.g. 11110001 b).

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't-care bits, e.g.:

```
SADDR 0101 0110b
SADEN 1111 1100b
SADDR OR SADEN1111 111Xb
```

The use of don't-care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

Slave A:SADDR1111 0001b
SADEN1111 1010b
Given1111 1X11b,

Slave B:SADDR1111 0011b
SADEN1111 1001b
Given1111 1X11B,

Slave C:SADDR=1111 0010b
SADEN1111 1101b
Given1111 1111b

## Registers

For slaves $A$ and $B$, bit 2 is a don't care bit; for slave $C$, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send and address FBh.

## Timers/Counters

## Timer/Counter Operations

## Timer 0

The A/T89C51AC2 implements two general-purpose, 16-bit Timers/Counters. Such are identified as Timer 0 and Timer 1, and can be independently configured to operate in a variety of modes as a Timer or an event Counter. When operating as a Timer, the Timer/Counter runs for a programmed length of time, then issues an interrupt request. When operating as a Counter, the Timer/Counter counts negative transitions on an external pin. After a preset number of counts, the Counter issues an interrupt request. The various operating modes of each Timer/Counter are described in the following sections.

A basic operation is Timer registers THx and $\operatorname{TLx}(x=0,1)$ connected in cascade to form a 16 -bit Timer. Setting the run control bit (TRx) in TCON register (see Figure 39) turns the Timer on by allowing the selected input to increment TLx. When TLx overflows it increments THx; when THx overflows it sets the Timer overflow flag (TFx) in TCON register. Setting the TRx does not clear the THx and TLx Timer registers. Timer registers can be accessed to obtain the current count or to enter preset values. They can be read at any time but TRx bit must be cleared to preset their values, otherwise the behavior of the Timer/Counter is unpredictable.

The C/Tx\# control bit selects Timer operation or Counter operation by selecting the divided-down peripheral clock or external pin Tx as the source for the counted signal. TRx bit must be cleared when changing the mode of operation, otherwise the behavior of the Timer/Counter is unpredictable.
For Timer operation ( $\mathrm{C} / \mathrm{Tx} \#=0$ ), the Timer register counts the divided-down peripheral clock. The Timer register is incremented once every peripheral cycle ( 6 peripheral clock periods). The Timer clock rate is $\mathrm{F}_{\text {PER }} / 6$, i.e. $\mathrm{F}_{\text {OSC }} / 12$ in standard mode or $\mathrm{F}_{\mathrm{OSC}} / 6$ in X2 mode.

For Counter operation (C/Tx\# = 1), the Timer register counts the negative transitions on the Tx external input pin. The external input is sampled every peripheral cycles. When the sample is high in one cycle and low in the next one, the Counter is incremented. Since it takes 2 cycles ( 12 peripheral clock periods) to recognize a negative transition, the maximum count rate is $\mathrm{F}_{\text {PER }} / 12$, i.e. $\mathrm{F}_{\text {OSc }} / 24$ in standard mode or $\mathrm{F}_{\mathrm{OSC}} / 12$ in X2 mode. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full peripheral cycle.

Timer 0 functions as either a Timer or event Counter in four modes of operation. Figure 31 to Figure 34 show the logical configuration of each mode.

Timer 0 is controlled by the four lower bits of TMOD register (see Figure 40) and bits 0 , 1, 4 and 5 of TCON register (see Figure 39). TMOD register selects the method of Timer gating (GATE0), Timer or Counter operation (T/C0\#) and mode of operation (M10 and M00). TCON register provides Timer 0 control functions: overflow flag (TFO), run control bit (TRO), interrupt flag (IEO) and interrupt type control bit (ITO).

For normal Timer operation (GATEO $=0$ ), setting TR0 allows TLO to be incremented by the selected input. Setting GATEO and TRO allows external pin INTO\# to control Timer operation.

Timer 0 overflow (count rolls over from all 1 s to all 0 s) sets TF0 flag generating an interrupt request.

It is important to stop Timer/Counter before changing mode.

Mode 0 (13-bit Timer)
Mode 0 configures Timer 0 as an 13-bit Timer which is set up as an 8-bit Timer (TH0 register) with a modulo 32 prescaler implemented with the lower five bits of TLO register (see Figure 31). The upper three bits of TL0 register are indeterminate and should be ignored. Prescaler overflow increments TH0 register.

Figure 31. Timer/Counter $x(x=0$ or 1$)$ in Mode 0
See the "Clock" section

Mode 1 (16-bit Timer)
Mode 1 configures Timer 0 as a 16-bit Timer with TH0 and TLO registers connected in cascade (see Figure 32). The selected input increments TLO register.

Figure 32. Timer/Counter $x(x=0$ or 1$)$ in Mode 1
See the "Clock" section

Mode 2 (8-bit Timer with AutoReload)

Mode 2 configures Timer 0 as an 8-bit Timer (TLO register) that automatically reloads from TH0 register (see Figure 33). TL0 overflow sets TF0 flag in TCON register and reloads TLO with the contents of TH0, which is preset by software. When the interrupt request is serviced, hardware clears TF0. The reload leaves TH0 unchanged. The next reload value may be changed at any time by writing it to TH0 register.

Figure 33. Timer/Counter $x(x=0$ or 1$)$ in Mode 2
See the "Clock" section

## Mode 3 (Two 8-bit Timers)

Mode 3 configures Timer 0 such that registers TLO and TH0 operate as separate 8 -bit Timers (see Figure 34). This mode is provided for applications requiring an additional 8bit Timer or Counter. TLO uses the Timer 0 control bits C/T0\# and GATE0 in TMOD register, and TR0 and TF0 in TCON register in the normal manner. TH0 is locked into a Timer function (counting $\mathrm{F}_{\text {PER }} / 6$ ) and takes over use of the Timer 1 interrupt (TF1) and run control (TR1) bits. Thus, operation of Timer 1 is restricted when Timer 0 is in mode 3.

Figure 34. Timer/Counter 0 in Mode 3: Two 8-bit Counters

## Timer 1

## Mode 0 (13-bit Timer)

## Mode 1 (16-bit Timer)

Mode 2 (8-bit Timer with AutoReload)

Mode 3 (Halt)

## Interrupt

Timer 1 is identical to Timer 0 excepted for Mode 3 which is a hold-count mode. The following comments help to understand the differences:

- Timer 1 functions as either a Timer or event Counter in three modes of operation. Figure 31 to Figure 33 show the logical configuration for modes 0,1 , and 2. Timer 1 's mode 3 is a hold-count mode.
- Timer 1 is controlled by the four high-order bits of TMOD register (see Figure 40) and bits 2, 3, 6 and 7 of TCON register (see Figure 39). TMOD register selects the method of Timer gating (GATE1), Timer or Counter operation (C/T1\#) and mode of operation (M11 and M01). TCON register provides Timer 1 control functions: overflow flag (TF1), run control bit (TR1), interrupt flag (IE1) and interrupt type control bit (IT1).
- Timer 1 can serve as the Baud Rate Generator for the Serial Port. Mode 2 is best suited for this purpose.
- For normal Timer operation (GATE1 $=0$ ), setting TR1 allows TL1 to be incremented by the selected input. Setting GATE1 and TR1 allows external pin INT1\# to control Timer operation.
- Timer 1 overflow (count rolls over from all 1s to all 0 s) sets the TF1 flag generating an interrupt request.
- When Timer 0 is in mode 3, it uses Timer 1's overflow flag (TF1) and run control bit (TR1). For this situation, use Timer 1 only for applications that do not require an interrupt (such as a Baud Rate Generator for the Serial Port) and switch Timer 1 in and out of mode 3 to turn it off and on.
- It is important to stop Timer/Counter before changing mode.

Mode 0 configures Timer 1 as a 13-bit Timer, which is set up as an 8 -bit Timer (TH1 register) with a modulo-32 prescaler implemented with the lower 5 bits of the TL1 register (see Figure 31). The upper 3 bits of TL1 register are ignored. Prescaler overflow increments TH1 register.

Mode 1 configures Timer 1 as a 16 -bit Timer with TH1 and TL1 registers connected in cascade (see Figure 32). The selected input increments TL1 register.

Mode 2 configures Timer 1 as an 8-bit Timer (TL1 register) with automatic reload from TH1 register on overflow (see Figure 33). TL1 overflow sets TF1 flag in TCON register and reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

Placing Timer 1 in mode 3 causes it to halt and hold its count. This can be used to halt Timer 1 when TR1 run control bit is not available i.e. when Timer 0 is in mode 3.

Each Timer handles one interrupt source that is the timer overflow flag TF0 or TF1. This flag is set every time an overflow occurs. Flags are cleared when vectoring to the Timer interrupt routine. Interrupts are enabled by setting ETx bit in IENO register. This assumes interrupts are globally enabled by setting EA bit in IENO register.

## Timer 2

## Auto-Reload Mode

The A/T89C51AC2 timer 2 is compatible with timer 2 in the 80C52.
It is a 16-bit timer/counter: the count is maintained by two eight-bit timer registers, TH2 and TL2 that are cascade- connected. It is controlled by T2CON register (See Table) and T2MOD register (See Table 47). Timer 2 operation is similar to Timer 0 and Timer 1. $\mathrm{C} / \overline{\mathrm{T} 2}$ selects $\mathrm{F}_{\mathrm{T} 2 \text { clock }} / 6$ (timer operation) or external pin T2 (counter operation) as timer clock. Setting TR2 allows TL2 to be incremented by the selected input.

Timer 2 includes the following enhancements:

- Auto-reload mode (up or down counter)
- Programmable clock-output

The auto-reload mode configures timer 2 as a 16-bit timer or event counter with automatic reload. This feature is controlled by the DCEN bit in T2MOD register (See Table 47). Setting the DCEN bit enables timer 2 to count up or down as shown in Figure 36. In this mode the T2EX pin controls the counting direction.
When T2EX is high, timer 2 counts up. Timer overflow occurs at FFFFh which sets the TF2 flag and generates an interrupt request. The overflow also causes the 16 -bit value in RCAP2H and RCAP2L registers to be loaded into the timer registers TH2 and TL2.
When T2EX is low, timer 2 counts down. Timer underflow occurs when the count in the timer registers TH2 and TL2 equals the value stored in RCAP2H and RCAP2L registers. The underflow sets TF2 flag and reloads FFFFh into the timer registers.
The EXF2 bit toggles when timer 2 overflow or underflow, depending on the direction of the count. EXF2 does not generate an interrupt. This bit can be used to provide 17-bit resolution.

Figure 36. Auto-Reload Mode Up/Down Counter
see section "Clock"

(UP COUNTING RELOAD VALUE)

## Programmable ClockOutput

In clock-out mode, timer 2 operates as a $50 \%$-duty-cycle, programmable clock generator (See Figure 37). The input clock increments TL2 at frequency $\mathrm{F}_{\mathrm{Osc}} / 2$. The timer repeatedly counts to overflow from a loaded value. At overflow, the contents of RCAP2H and RCAP2L registers are loaded into TH2 and TL2. In this mode, timer 2 overflows do not generate interrupts. The formula gives the clock-out frequency depending on the system oscillator frequency and the value in the RCAP2H and RCAP2L registers:

$$
\text { Clock }- \text { OutFrequency }=\frac{F T 2 \text { clock }}{4 \times(65536-\text { RCAP } 2 H / R C A P 2 L)}
$$

For a 16 MHz system clock in x 1 mode, timer 2 has a programmable frequency range of $61 \mathrm{~Hz}\left(\mathrm{~F}_{\mathrm{OSC}} / 2^{16)}\right.$ to $4 \mathrm{MHz}(\mathrm{Fosc} / 4)$. The generated clock signal is brought out to T 2 pin (P1.0).
Timer 2 is programmed for the clock-out mode as follows:

- Set T2OE bit in T2MOD register.
- Clear C/T2 bit in T2CON register.
- Determine the 16 -bit reload value from the formula and enter it in RCAP2H/RCAP2L registers.
- Enter a 16-bit initial value in timer registers TH2/TL2. It can be the same as the reload value or different depending on the application.
- To start the timer, set TR2 run control bit in T2CON register.

It is possible to use timer 2 as a baud rate generator and a clock generator simultaneously. For this configuration, the baud rates and clock frequencies are not independent since both functions use the values in the RCAP2H and RCAP2L registers.

## Watchdog Timer

Figure 38. Watchdog Timer

A/T89C51AC2 contains a powerful programmable hardware Watchdog Timer (WDT) that automatically resets the chip if it software fails to reset the WDT before the selected time interval has elapsed. It permits large Time-Out ranking from 16 ms to $2 \mathrm{~s} @ \mathrm{Fosc}=$ 12 MHz in X 1 mode.

This WDT consists of a 14-bit counter plus a 7 -bit programmable counter, a Watchdog Timer reset register (WDTRST) and a Watchdog Timer programming (WDTPRG) register. When exiting reset, the WDT is -by default- disable.

To enable the WDT, the user has to write the sequence 1EH and E1H into WDTRST register no instruction in between. When the Watchdog Timer is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will generate an output RESET pulse at the RST pin. The RESET pulse duration is $96 \times T_{\text {osc }}$, where $T_{\text {osc }}=1 / F_{\text {osc }}$. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset
Note: When the Watchdog is enable it is impossible to change its period.

Watchdog Programming
The three lower bits (S0, S1, S2) located into WDTPRG register permit to program the WDT duration.

Table 51. Machine Cycle Count

| S2 | S1 | Machine Cycle Count |  |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | $2^{14}-1$ |
| 0 | 0 | 1 | $2^{15}-1$ |
| 0 | 1 | 0 | $2^{16}-1$ |
| 0 | 1 | 1 | $2^{17}-1$ |
| 1 | 0 | 0 | $2^{18}-1$ |
| 1 | 1 | 0 | $2^{19}-1$ |
| 1 | 1 | 1 | $2^{20}-1$ |
| 1 | 0 | $2^{21}-1$ |  |

To compute WD Time-Out, the following formula is applied:

$$
\text { FTime }- \text { Out }=\frac{F_{\text {osc }}}{6 \times 2^{W D X 2 \wedge X 2}\left(2^{14} \times 2^{\text {Svalue }}\right)}
$$

Note: Svalue represents the decimal value of (S2 S1 S0)

The following table outlines the time-out value for $\mathrm{Fosc}_{\text {XTAL }}=12 \mathrm{MHz}$ in X 1 mode

Table 52. Time-Out Computation

| 1 | 1 | 0 | 1.05 s | 786.24 ms | 629.12 ms |
| 1 | 1 | 1 | 2.10 s | 1.57 s | 1.25 s |

## Watchdog Timer During Power-down Mode and Idle

In Power-down mode the oscillator stops, which means the WDT also stops. While in Power-down mode, the user does not need to service the WDT. There are 2 methods of exiting Power-down mode: by a hardware reset or via a level activated external interrupt which is enabled prior to entering Power-down mode. When Power-down is exited with hardware reset, the Watchdog is disabled. Exiting Power-down with an interrupt is significantly different. The interrupt shall be held low long enough for the oscillator to stabilize. When the interrupt is brought high, the interrupt is serviced. To prevent the WDT from resetting the device while the interrupt pin is held low, the WDT is not started until the interrupt is pulled high. It is suggested that the WDT be reset during the interrupt service for the interrupt used to exit Power-down.

To ensure that the WDT does not overflow within a few states of exiting powerdown, it is best to reset the WDT just before entering powerdown.

In the Idle mode, the oscillator continues to run. To prevent the WDT from resetting A/T89C51AC2 while in Idle mode, the user should always set up a timer that will periodically exit Idle, service the WDT, and re-enter Idle mode.

## Programmable Counter Array (PCA)

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of five compare/capture modules. Its clock input can be programmed to count any of the following signals:

- PCA clock frequency/6 (see "clock" section)
- PCA clock frequency/2
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture modules can be programmed in any one of the following modes:

- rising and/or falling edge capture,
- software timer,
- high-speed output,
- pulse width modulator.

Module 4 can also be programmed as a Watchdog timer. see the "PCA Watchdog Timer" section.

When the compare/capture modules are programmed in capture mode, software timer, or high speed output mode, an interrupt can be generated when the module executes its function. All five modules plus the PCA timer overflow share one interrupt vector.

The PCA timer/counter and compare/capture modules share Port 1 for external I/Os. These pins are listed below. If the port is not used for the PCA, it can still be used for standard I/O.

| PCA Component | External I/O Pin |
| :---: | :---: |
| 16-bit Counter | P1.2/ECI |
| 16-bit Module 0 | P1.3/CEX0 |
| 16-bit Module 1 | P1.4/CEX1 |
| 16-bit Module 2 | P1.5/CEX2 |
| 16-bit Module 3 | P1.6/CEX3 |
| 16-bit Module 4 | P1.7/CEX4 |

## PCA Timer

The PCA timer is a common time base for all five modules (see Figure 39). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD SFR (see Table 8) and can be programmed to run at:

- $1 / 6$ the PCA clock frequency.
- $1 / 2$ the PCA clock frequency.
- the Timer 0 overflow.
- the input on the ECI pin (P1.2).

Figure 39. PCA Timer/Counter

The CMOD register includes three additional bits associated with the PCA.

- The CIDL bit which allows the PCA to stop during idle mode.
- The WDTE bit which enables or disables the Watchdog function on module 4.
- The ECF bit which when set causes an interrupt and the PCA overflow flag CF in CCON register to be set when the PCA timer overflows.

The CCON register contains the run control bit for the PCA and the flags for the PCA timer and each module.

- The CR bit must be set to run the PCA. The PCA is shut off by clearing this bit.
- The CF bit is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in CMOD register is set. The CF bit can only be cleared by software.
- The CCFO:4 bits are the flags for the modules (CCFO for module0...) and are set by hardware when either a match or a capture occurs. These flags also can be cleared by software.

## PCA Modules

Each one of the five compare/capture modules has six possible functions. It can perform:

- 16-bit Capture, positive-edge triggered
- 16-bit Capture, negative-edge triggered
- 16-bit Capture, both positive and negative-edge triggered
- 16-bit Software Timer
- 16-bit High Speed Output
- 8 -bit Pulse Width Modulator.

In addition module 4 can be used as a Watchdog Timer.

Each module in the PCA has a special function register associated with it (CCAPM0 for module 0...). The CCAPM0:4 registers contain the bits that control the mode that each module will operate in.

- The ECCF bit enables the CCF flag in the CCON register to generate an interrupt when a match or compare occurs in the associated module.
- The PWM bit enables the pulse width modulation mode.
- The TOG bit when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register.
- The match bit MAT when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.
- The two bits CAPN and CAPP in CCAPMn register determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled.
- The bit ECOM in CCAPM register when set enables the comparator function.

## PCA Interrupt

Figure 40. PCA Interrupt System

## PCA Capture Mode

To use one of the PCA modules in capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated.

Figure 41. PCA Capture Mode

## 16-bit Software Timer Mode

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set.

Figure 42. PCA 16-bit Software Timer and High Speed Output Mode

| :---: | :---: |

Reset Write to CCAPnL
Write to CCAPnH

位ware Timer mode, set ECOMn and MATn. For high speed output mode, set ECOMn, MATn and TOGn.

High Speed Output Mode
In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set.

Figure 43. PCA High Speed Output Mode

## Pulse Width Modulator

 ModeAll the PCA modules can be used as PWM outputs. The output frequency depends on the source for the PCA timer. All the modules will have the same output frequency because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than it, the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. the allows the PWM to be updated without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

Figure 44. PCA PWM Mode

## PCA Watchdog Timer

An on-board Watchdog timer is available with the PCA to improve system reliability without increasing chip count. Watchdog timers are useful for systems that are sensitive to noise, power glitches, or electrostatic discharge. Module 4 is the only PCA module that can be programmed as a Watchdog. However, this module can still be used for other modes if the Watchdog is not needed. The user pre-loads a 16-bit value in the compare registers. Just like the other compare modes, this 16 -bit value is compared to the PCA timer value. If a match is allowed to occur, an internal reset will be generated. This will not cause the RST pin to be driven high.

To hold off the reset, the user has three options:

- periodically change the compare value so it will never match the PCA timer,
- periodically change the PCA timer value so it will never match the compare values, or
- disable the Watchdog by clearing the WDTE bit before a match occurs and then reenable it.

The first two options are more reliable because the Watchdog timer is never disabled as in the third option. If the program counter ever goes astray, a match will eventually occur and cause an internal reset. If other PCA modules are being used the second option not recommended either. Remember, the PCA timer is the time base for all modules; changing the time base for other modules would not be a good idea. Thus, in most applications the first solution is the best option.

## Analog-to-Digital Converter (ADC)

## Features

- 8 channels with multiplexed inputs
- 10-bit cascaded potentiometric ADC
- Conversion time 16 micro-seconds (typ.)
- Zero Error (offset) $\pm 2$ LSB max
- Positive External Reference Voltage Range (VAREF) 2.4 to 3.0 Volt (typ.)
- ADCIN Range 0 to 3Volt
- Integral non-linearity typical 1 LSB, max. 2 LSB
- Differential non-linearity typical 0.5 LSB, max. 1 LSB
- Conversion Complete Flag or Conversion Complete Interrupt
- Selectable ADC Clock

## ADC Port 1 I/O Functions

Port 1 pins are general I/O that are shared with the ADC channels. The channel select bit in ADCF register define which ADC channel/port1 pin will be used as ADCIN. The remaining ADC channels/port1 pins can be used as general-purpose I/O or as the alternate function that is available.
A conversion launched on a channel which are not selected on ADCF register will not have any effect.

VAREF should be connected to a low impedance point and must remain in the range specified in Table 77. If the ADC is not used, it is recommended to connect VAREF to VAGND.

Figure 45. ADC Description

Figure 46 shows the timing diagram of a complete conversion. For simplicity, the figure depicts the waveforms in idealized form and do not provide precise timing information. For ADC characteristics and timing parameters refer to the Section "AC Characteristics" of the A/T89C51AC2 datasheet.

Figure 46. Timing Diagram

Notes: 1. Tsetup min, see the AC Parameter for A/D conversion.
2. Tconv $=11$ clock $\operatorname{ADC}=1$ sample and hold +10 bit conversion The user must ensure that Tsetup time between setting ADEN and the start of the first conversion.

ADC Converter Operation

A start of single A/D conversion is triggered by setting bit ADSST (ADCON.3).
After completion of the A/D conversion, the ADSST bit is cleared by hardware.
The end-of-conversion flag ADEOC (ADCON.4) is set when the value of conversion is available in ADDH and ADDL, it must be cleared by software. If the bit EADC (IEN1.1) is set, an interrupt occur when flag ADEOC is set (see Figure 48). Clear this flag for rearming the interrupt.

The bits SCH0 to SCH2 in ADCON register are used for the analog input channel selection. ${ }^{(1)}$
Note: 1. Always leave Tsetup time before starting a conversion unless ADEN is permanently high. In this case one should wait Tsetup only before the first conversion.

Table 62. Selected Analog input

| SCH2 | SCH1 | SCH0 | Selected Analog input |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | AN0 |
| 0 | 0 | 1 | AN1 |
| 0 | 1 | 0 | AN2 |
| 0 | 1 | 1 | AN3 |
| 1 | 0 | 0 | AN4 |
| 1 | 0 | 1 | AN5 |
| 1 | 1 | 0 | AN6 |
| 1 | 1 | 1 | AN7 |

Voltage Conversion

Clock Selection

When the ADCIN is equals to VAREF the ADC converts the signal to $3 F F h$ (full scale). If the input voltage equals VAGND, the ADC converts it to 000 h . Input voltage between VAREF and VAGND are a straight-line linear conversion. All other voltages will result in 3FFh if greater than VAREF and 000h if less than VAGND.
Note: ADCIN should not exceed VAREF absolute maximum range (see "Absolute Maximum Ratings" on page 141)

The ADC clock is the same as CPU.
The maximum clock frequency is defined in the DC parmeter for A/D converter. A prescaler is featured (ADCCLK) to generate the ADC clock from the oscillator frequency.
if $P R S>0$ then $f_{A D C}=F_{\text {periph }} / 2 \times$ PRS
if $P R S=0$ then $f_{A D C}=F_{\text {periph }} / 64$

Figure 47. A/D Converter clock

## ADC Standby Mode

## IT ADC Management

When the ADC is not used, it is possible to set it in standby mode by clearing bit ADEN in ADCON register. In this mode its power dissipation is reduced.

An interrupt end-of-conversion will occurs when the bit ADEOC is activated and the bit EADC is set. For re-arming the interrupt the bit ADEOC must be cleared by software.

Figure 48. ADC Interrupt Structure

Routines examples

1. Configure P1.2 and P1.3 in ADC channels
```
// configure channel P1.2 and P1.3 for ADC
    ADCF = 0Ch
// Enable the ADC
        ADCON = 20h
```

2. Start a standard conversion
```
// The variable "channel" contains the channel to convert
// The variable "value_converted" is an unsigned int
// Clear the field SCH[2:0]
    ADCON and = F8h
// Select channel
    ADCON | = channel
// Start conversion in standard mode
    ADCON | = 08h
// Wait flag End of conversion
    while((ADCON and 01h)! = 01h)
// Clear the End of conversion flag
    ADCON and = EFh
// read the value
    value_converted =(ADDH << 2) +(ADDL)
```

3. Start a precision conversion (need interrupt ADC)
```
// The variable "channel" contains the channel to convert
// Enable ADC
EADC = 1
```

// clear the field SCH[2:0]
ADCON and $=\mathrm{F} 8 \mathrm{~h}$
// Select the channel
ADCON | = channel
// Start conversion in precision mode
$\mathrm{ADCON} \mid=48 \mathrm{~h}$

Note: to enable the ADC interrupt:
$E A=1$

## Interrupt System

## Introduction

The controller has a total of 8 interrupt vectors: two external interrupts ( $\overline{\text { INTO }}$ and $\overline{\text { INT1 }}$ ), three timer interrupts (Timers 0,1 and 2), a serial port interrupt, a PCA, a timer overrun interrupt and an ADC. These interrupts are shown below.

Figure 49. Interrupt Control System

Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable register. This register also contains a global disable bit which must be cleared to disable all the interrupts at the same time.

Each interrupt source can also be individually programmed to one of four priority levels by setting or clearing a bit in the Interrupt Priority registers. The Table below shows the bit values and priority levels associated with each combination.

Table 68. Priority Level Bit Values

| IPH.x | IPL.x | Interrupt Level Priority |
| :---: | :---: | :---: |
| 0 | 0 | 0 (Lowest) |
| 0 | 1 | 1 |
| 1 | 0 | 2 |
| 1 | 1 | 3 (Highest) |

A low-priority interrupt can be interrupted by a high priority interrupt but not by another low-priority interrupt. A high-priority interrupt cannot be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of the higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence, see Table 69.

Table 69. Interrupt Priority Within level

| Interrupt Name | Interrupt Address Vector | Priority Number |
| :---: | :---: | :---: |
| external interrupt (INT0) | 0003 h | 1 |

## Electrical Characteristics

## Absolute Maximum Ratings*

| Ambiant Temperature Under Bias: |  |
| :---: | :---: |
| $\mathrm{I}=$ industrial ................................................. $40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ |  |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Voltage on $\mathrm{V}_{\text {CC }}$ from $\mathrm{V}_{\text {SS }} \ldots \ldots . . .$. | ....-0.5V to +6 V |
| Voltage on Any Pin from $\mathrm{V}_{\text {SS }} \ldots \ldots$. | . 5 V to $\mathrm{V}_{\mathrm{CC}}+0.2 \mathrm{~V}$ |
| Power Dissipation | .... 1W |

*NOTICE: Stresses at or above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability. The power dissipation is based on the maximum allowable die temperature and the thermal resistance of the package.

## DC Parameters for Standard Voltage

$\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C} ; \mathrm{V}_{\mathrm{SS}}=0 \mathrm{~V} ; \mathrm{V}_{\mathrm{CC}}=3 \mathrm{~V}$ to $5.5 \mathrm{~V} ; \mathrm{F}=0$ to 40 MHz
Table 76. DC Parameters in Standard Voltage

| Symbol | Parameter | Min | Typ ${ }^{(5)}$ | Max | Unit | Test Conditions |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {IL }}$ | Input Low Voltage | -0.5 |  | 0.2Vcc - 0.1 | V |  |
| $\mathrm{V}_{\mathrm{IH}}$ | Input High Voltage except XTAL1, RST | $0.2 \mathrm{~V}_{\mathrm{CC}}+0.9$ |  | $\mathrm{V}_{\mathrm{CC}}+0.5$ | V |  |
| $\mathrm{V}_{\mathrm{HH} 1}$ | Input High Voltage, XTAL1, RST | $0.7 \mathrm{~V}_{\text {CC }}$ |  | $\mathrm{V}_{\mathrm{CC}}+0.5$ | V |  |
| $\mathrm{V}_{\mathrm{OL}}$ | Output Low Voltage, ports 1, 2, 3 and $4^{(6)}$ |  |  | $\begin{gathered} 0.3 \\ 0.45 \\ 1.0 \end{gathered}$ | $\begin{aligned} & \mathrm{V} \\ & \mathrm{~V} \\ & \mathrm{~V} \end{aligned}$ | $\begin{aligned} & \mathrm{I}_{\mathrm{OL}}=100 \mu \mathrm{~A}^{(4)} \\ & \mathrm{I}_{\mathrm{OL}}=1.6 \mathrm{~mA}^{(4)} \\ & \mathrm{I}_{\mathrm{OL}}=3.5 \mathrm{~mA}^{(4)} \end{aligned}$ |
| $\mathrm{V}_{\text {OL1 }}$ | Output Low Voltage, port 0, ALE, $\overline{\text { PSEN }}^{(6)}$ |  |  | $\begin{gathered} 0.3 \\ 0.45 \\ 1.0 \end{gathered}$ | $\begin{aligned} & \mathrm{V} \\ & \mathrm{~V} \\ & \mathrm{~V} \end{aligned}$ | $\begin{aligned} & \mathrm{I}_{\mathrm{OL}}=200 \mu \mathrm{~A}^{(4)} \\ & \mathrm{I}_{\mathrm{OL}}=3.2 \mathrm{~mA}^{(4)} \\ & \mathrm{I}_{\mathrm{OL}}=7.0 \mathrm{~mA}^{(4)} \end{aligned}$ |
| $\mathrm{V}_{\mathrm{OH}}$ | Output High Voltage, ports 1, 2, 3, 4 and 5 | $\mathrm{V}_{\mathrm{CC}}-0.3$ <br> $\mathrm{V}_{\mathrm{CC}}-0.7$ <br> $V_{C C}-1.5$ |  |  | $\begin{aligned} & \mathrm{V} \\ & \mathrm{~V} \\ & \mathrm{~V} \end{aligned}$ | $\begin{aligned} & \mathrm{l}_{\mathrm{OH}}=-10 \mu \mathrm{~A} \\ & \mathrm{I}_{\mathrm{OH}}=-30 \mu \mathrm{~A} \\ & \mathrm{I}_{\mathrm{OH}}=-60 \mu \mathrm{~A} \end{aligned}$ |
| $\mathrm{V}_{\text {OH1 }}$ | Output High Voltage, port 0, ALE, $\overline{\text { PSEN }}$ | $V_{C C}-0.3$ <br> $\mathrm{V}_{\mathrm{CC}}-0.7$ <br> $\mathrm{V}_{\mathrm{CC}}-1.5$ |  |  | $\begin{aligned} & \mathrm{V} \\ & \mathrm{v} \\ & \mathrm{~V} \end{aligned}$ | $\begin{aligned} & \mathrm{I}_{\mathrm{OH}}=-200 \mu \mathrm{~A} \\ & \mathrm{I}_{\mathrm{OH}}=-3.2 \mathrm{~mA} \\ & \mathrm{I}_{\mathrm{OH}}=-7.0 \mathrm{~mA} \end{aligned}$ |
| $\mathrm{R}_{\text {RST }}$ | RST Pulldown Resistor | 20 | 40 | 200 | k $\Omega$ |  |
| $1 / L$ | Logical 0 Input Current ports 1, 2, 3 and 4 |  |  | -50 | $\mu \mathrm{A}$ | $\mathrm{Vin}=0.45 \mathrm{~V}$ |
| $\mathrm{I}_{\mathrm{LI}}$ | Input Leakage Current |  |  | $\pm 10$ | $\mu \mathrm{A}$ | $0.45 \mathrm{~V}<\mathrm{Vin}<\mathrm{V}_{\text {c }}$ |
| $\mathrm{I}_{\text {TL }}$ | Logical 1 to 0 Transition Current, ports 1, 2, 3 and 4 |  |  | -650 | $\mu \mathrm{A}$ | $\mathrm{Vin}=2.0 \mathrm{~V}$ |
| $\mathrm{C}_{10}$ | Capacitance of I/O Buffer |  |  | 10 | pF | $\begin{aligned} & \mathrm{Fc}=1 \mathrm{MHz} \\ & \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C} \end{aligned}$ |
| $\mathrm{IPD}^{\text {P }}$ | Power-down Current |  | 160 | 350 | $\mu \mathrm{A}$ | $3 \mathrm{~V}<\mathrm{V}_{\mathrm{CC}}<5.5 \mathrm{~V}^{(3)}$ |
| $\mathrm{I}_{\mathrm{cc}}$ | Power Supply Current | $\begin{gathered} \mathrm{I}_{\mathrm{CCOP}}=0.7 \text { Freq }(\mathrm{MHz})+3 \mathrm{~mA} \\ \text { ICC_FLASH_WRITE }^{(7)}=0.4 \mathrm{Freq}(\mathrm{MHz})+20 \mathrm{~mA} \\ \mathrm{I}_{\text {CCIDLE }}=0.6 \text { Freq }(\mathrm{MHz})+2 \mathrm{~mA} \end{gathered}$ |  |  |  | $3 \mathrm{~V}<\mathrm{V}_{\mathrm{CC}}<5.5 \mathrm{~V}^{(1)(2)}$ |

Notes: 1. Operating $I_{C C}$ is measured with all output pins disconnected; XTAL1 driven with $\mathrm{T}_{\mathrm{CLCH}}, \mathrm{T}_{\mathrm{CHCL}}=5 \mathrm{~ns}$ (see Figure 53.), $\mathrm{V}_{\mathrm{IL}}=\mathrm{V}_{\mathrm{SS}}+0.5 \mathrm{~V}$,
$\mathrm{V}_{\mathrm{IH}}=\mathrm{V}_{\mathrm{CC}}-0.5 \mathrm{~V}$; XTAL2 N.C.; EA $=\mathrm{RST}=$ Port $0=\mathrm{V}_{\mathrm{CC}} . \mathrm{I}_{\mathrm{CC}}$ would be slightly higher if a crystal oscillator used (see Figure 50.).
2. Idle $\mathrm{I}_{\mathrm{CC}}$ is measured with all output pins disconnected; XTAL1 driven with $\mathrm{T}_{\mathrm{CLCH}}$, $\mathrm{T}_{\mathrm{CHCL}}=5 \mathrm{~ns}, \mathrm{~V}_{\mathrm{IL}}=\mathrm{V}_{\mathrm{SS}}+0.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{IH}}=\mathrm{V}_{\mathrm{CC}}-0.5 \mathrm{~V}$; XTAL2 N.C; Port $0=\mathrm{V}_{\mathrm{CC}} ; \overline{\mathrm{EA}}=\mathrm{RST}$ $=V_{S S}$ (see Figure 51.).
3. Power-down $\mathrm{I}_{\mathrm{CC}}$ is measured with all output pins disconnected; $\overline{\mathrm{EA}}=\mathrm{V}_{\mathrm{CC}}, \mathrm{PORT} 0=$ $\mathrm{V}_{\mathrm{CC}}$; XTAL2 NC.; RST $=\mathrm{V}_{\mathrm{SS}}$ (see Figure 52.). In addition, the WDT must be inactive and the POF flag must be set.
4. Capacitance loading on Ports 0 and 2 may cause spurious noise pulses to be superimposed on the $\mathrm{V}_{\mathrm{OL}} \mathrm{S}$ of ALE and Ports 1 and 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make 1 to 0 transitions during bus operation. In the worst cases (capacitive loading 100pF), the noise pulse on the ALE line may exceed 0.45 V with maxi $\mathrm{V}_{\text {OL }}$ peak 0.6 V . A Schmitt Trigger use is not necessary.
5. Typicals are based on a limited number of samples and are not guaranteed. The values listed are at room temperature.
6. Under steady state (non-transient) conditions, $\mathrm{I}_{\mathrm{OL}}$ must be externally limited as follows:
Maximum Iol per port pin: 10 mA
Maximum $\mathrm{I}_{\mathrm{OL}}$ per 8-bit port:
Port 0: 26 mA
Ports 1, 2 and 3: 15 mA
Maximum total $\mathrm{I}_{\mathrm{OL}}$ for all output pins: 71 mA
If $\mathrm{I}_{\mathrm{OL}}$ exceeds the test condition, $\mathrm{V}_{\mathrm{OL}}$ may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
7. ICC_FLASH_WRITE operating current while a Flash block write is on going.

## DC Parameters for A/D Converter

Table 77. DC Parameters for AD Converter in Precision Conversion

| Symbol | Parameter | Min | Typ ${ }^{(1)}$ | Max | Unit | Test Conditions |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| AVin | Analog input voltage | Vss- 0.2 |  | Vref +0.2 | V |  |
| Rref ${ }^{(2)}$ | Resistance between Vref and Vss | 12 | 16 | 24 | k $\Omega$ |  |
| Vref | Reference voltage | 2.40 |  | 3.00 | V |  |
| Cai | Analog input Capacitance |  | 60 |  | pF | During sampling |
| Rai | Analog input Resistor |  |  | 400 | $\Omega$ | During sampling |
| INL | Integral non linearity |  | 1 | 2 | Isb |  |
| DNL | Differential non linearity |  | 0.5 | 1 | Isb |  |
| OE | Offset error | -2 |  | 2 | Isb |  |

Notes: 1. Typicals are based on a limited number of samples and are not guaranteed.
2. With ADC enabled.

## AC Parameters

## Explanation of the AC Symbols

Each timing symbol has 5 characters. The first character is always a "T" (stands for time). The other characters, depending on their positions, stand for the name of a signal or the logical status of that signal. The following is a list of all the characters and what they stand for.
Example: $\mathrm{T}_{\text {AVLL }}=$ Time for Address Valid to ALE Low.
$\mathrm{T}_{\text {LLPL }}=$ Time for ALE Low to $\overline{\text { PSEN }}$ Low.
$\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C} ; \mathrm{V}_{\mathrm{SS}}=0 \mathrm{~V} ; \mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V} \pm 10 \% ; \mathrm{F}=0$ to 40 MHz .
$\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C} ; \mathrm{V}_{\mathrm{SS}}=0 \mathrm{~V} ; \mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V} \pm 10 \%$.
(Load Capacitance for port 0, ALE and PSEN $=60 \mathrm{pF}$; Load Capacitance for all other outputs $=60 \mathrm{pF}$.)
Table 78, Table 81 and Table 84 give the description of each AC symbols.
Table 79, Table 83 and Table 85 give for each range the AC parameter.
Table 80, Table 83 and Table 86 give the frequency derating formula of the AC parameter for each speed range description. To calculate each AC symbols: Take the $x$ value and use this value in the formula.

Example: T $_{\text {LIIV }}$ and 20 MHz , Standard clock.
$\mathrm{x}=30 \mathrm{~ns}$
$\mathrm{T}=50 \mathrm{~ns}$
$\mathrm{T}_{\mathrm{CCIV}}=4 \mathrm{~T}-\mathrm{x}=170 \mathrm{~ns}$

External Program Memory Characteristics

Table 78. Symbol Description

| Symbol | Parameter |

| $\mathrm{~T}_{\text {CLCH }}$ | Rise Time |  | 5 | ns |
| $\mathrm{~T}_{\text {CHCL }}$ | Fall Time |  | 5 | ns |
| $\mathrm{~T}_{\text {CHCX }} / \mathrm{T}_{\text {CLCX }}$ | Cyclic ratio in X2 mode | 40 | 60 | $\%$ |

## External Clock Drive

## Waveforms

AC Testing Input/Output Waveforms

INPUT/OUTPUT

AC inputs during testing are driven at $\mathrm{V}_{\mathrm{CC}}-0.5$ for a logic " 1 " and 0.45 V for a logic " 0 ". Timing measurement are made at $\mathrm{V}_{\mathrm{IH}}$ min for a logic " 1 " and $\mathrm{V}_{\mathrm{IL}}$ max for a logic " 0 ".

## Float Waveforms

For timing purposes as port pin is no longer floating when a 100 mV change from load voltage occurs and begins to float when a 100 mV change from the loaded $\mathrm{V}_{\mathrm{OH}} / \mathrm{V}_{\mathrm{OL}}$ level occurs. $\mathrm{I}_{\mathrm{LL}} \mathrm{I}_{\mathrm{OH}} \geq \pm 20 \mathrm{~mA}$.

Clock Waveforms Valid in normal clock mode. In X2 mode XTAL2 must be changed to XTAL2/2.

## PORT OPERATION

MOV PORT SRC OLD DATA NEW DATA

This diagram indicates when signals are clocked internally. The time it takes the signals to propagate to the pins, however, ranges from 25 to 125 ns . This propagation delay is dependent on variables such as temperature and pin loading. Propagation also varies from output to output and component. Typically though ( $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ fully loaded) $\overline{\mathrm{RD}}$ and $\overline{\mathrm{WR}}$ propagation delays are approximately 50 ns . The other signals are typically 85 ns . Propagation delays are incorporated in the AC specifications.

## Flash/EEPROM Memory

Table 88. Timing Symbol Definitions

| Signals |  |
| :--- | :--- |
| S (Hardware <br> condition) | PSEN\#,EA |
| R | RST |
| B | FBUSY flag |

| Conditions |  |
| :--- | :--- |
| L | Low |
| V | Valid |
| X | No Longer Valid |

Table 89. Memory AC Timing

## Datasheet Change

Log for A/T89C51AC2

Changes from 4127D 02/03 to 4127E-01/05

Changes from 4127E01/05 to 4127F - 03/05

Changes from 4127F 03/05 to 4127G-05/06

1. Changed value of IPDMAX to 400, Section "Electrical Characteristics", page 101.
2. PCA , CPSO, register correction, Section "PCA Registers", page 81.
3. Cross Memory section added. Section "Operation Cross Memory Access", page 44.
4. Changed product part number from "T89C51AC2" to "A/T89C51AC2".
5. Added "Green" product ordering information.
6. Clarification to Mode Switching Waveform diagrams. See page page 16.
7. Minor corrections throughout the document.

## Changes from 4127G -

1. Removal of non-green part numbers from ordering information.
