

Description

The ZXGD3102 is intended to drive MOSFETs configured as ideal diode replacements. The device is comprised of a differential amplifier detector stage and high current driver. The detector monitors the reverse voltage of the MOSFET such that if body diode conduction occurs a positive voltage is applied to the MOSFET's Gate pin.

Once the positive voltage is applied to the Gate the MOSFET switches on allowing reverse current flow. The detectors' output voltage is then proportional to the MOSFET Drain-Source reverse voltage drop and this is applied to the Gate via the driver. This action provides a rapid turn off as current decays.

Features

- Turn-off time typically 105ns
- 180V blocking voltage
- Proportional Gate drive
- 2A Source, 5A Sink driver
- V_{CC} Range 5-15V
- Low component count

Applications

- High Side OR'ing diode replacement for Servers, Computer
- Low Side OR'ing diode replacement for Telecoms
- Ideal diode applications

Schematic Symbol and Pin Out Details

Pin No.	Symbol	Description and function
1	NC	No connection This pin can be connected to GND
2	REF	Reference This pin is connected to V_{CC} via resistor, R_{REF} . R_{REF} should be selected to source approximately 2.4mA into this pin. See Note 1
3	GATEL	Gate turn off This pin sinks current, I_{SINK} , from the OR'ing MOSFET Gate
4	GATEH	Gate turn on This pin sources current, I_{SOURCE} , to the OR'ing MOSFET Gate
5	V_{CC}	Power Supply This is the supply pin. Decouple this point to ground with a ceramic capacitor
6	GND	Ground This is the ground reference point. Connect to the OR'ing MOSFET Source terminal
7	BIAS	Bias This pin is connected to V_{CC} via R_{BIAS} . R_{BIAS} should be selected to source either 1 or 1.2 times I_{REF} into this pin depending on the desired turn-off threshold voltage, V_T . See Note 1
8	DRAIN	Drain connection This pin connects directly to the OR'ing MOSFET Drain terminal

Note 1- **BIAS** and **REF** pins should be assumed to be at **GND+0.7V**.

Operation

The operation of the device is described step-by-step with reference to the timing diagram below.

1. The detector monitors the MOSFET Drain-Source voltage.
2. At system start up, the MOSFET body diode is forced to conduct current from the input power supply to the load and there is approximately -0.6V on the Drain pin.
3. The detector outputs a positive voltage with respect to ground, this voltage is then fed to the MOSFET driver stage and current is sourced out of the GATEH pin. The turn on time of the MOSFET can be programmed through an external resistor R_G . Refer to "Speed vs. Gate resistance" graph.
4. The current out of the GATEH pin is sourced into the OR'ing MOSFET Gate to turn the device on.
5. The GATEH output voltage is proportional to the Drain-Source voltage drop across the MOSFET due to the load current flowing through the MOSFET. The controller increases its output gate voltage when the Drain current is high to ensure full MOSFET enhancement
6. If a short condition occurs on the input power supply it causes the OR'ing MOSFET Drain current to fall very quickly.
7. When the Drain-Source differential voltage drops below the turn off threshold, the MOSFET Gate voltage is pulled low by GATEL, turning the device off. This prevents high reverse current flow from the load to the input power supply which could pull down the common bus voltage causing catastrophic system failure

Component Selection

It is advisable to decouple the ZXGD3102 closely to V_{CC} and ground due to the possibility of high peak gate currents, as indicated by C1 in Figure 4. In applications where the input voltage is higher than 12V, it is recommended to use a Zener diode, ZD1 as shown in the Typical Application Circuit on page 1, and in Figure 2, in order to limit the V_{CC} supply voltage to the ZXGD3102 and also to limit the maximum voltage applied to the gate of the MOSFET. A suitable value for the Zener is 10V.

The proper selection of external resistors R_{REF} and R_{BIAS} is important to the optimum device operation. Select a value for resistor R_{REF} to give a reference current, I_{REF} , of ~2.4mA. The value of R_{BIAS} must then be selected to give a bias current, I_{BIAS} , of approximately 1.2 times I_{REF} . This sets the turn-off threshold voltage V_T of the controller to '-24mV' at $V_{CC} = 10V$.

$$R_{REF} = (V_{CC} - 0.7V) / 0.0024$$

$$R_{BIAS} = (V_{CC} - 0.7V) / 0.0028$$

Alternatively, R_{REF} and R_{BIAS} can be chosen to be equal to set the turn-off threshold voltage V_T to '-29mV' at $V_{CC} = 10V$. This also reduces the IC current consumption when the gate voltage is off.

External gate resistor to GATEH pin is optional. It can be inserted to control the turn-on gate rise time which may help with in-rush current protection, EMI issues or power dissipation within the part. The addition of C_{BIAS} controls the switch-on delay of the MOSFET, and ensures stability. A suitable value is 1nF.

Layout considerations

The Gate pins should be as close to the MOSFET gate as possible. Also the ground return loop should be as short as possible. The decoupling capacitor should be close to the V_{CC} and Ground pin, and should be a X7R type. Trace widths should be maximized in the high current path through the MOSFET and ground return in order to minimize the effects of circuit inductance and resistance.

For best thermal performance, the PCB heat path from pins 5 and 6 needs attention. The area of copper connected to pins 5 and 6 should be maximised.

Active OR'ing or N+1 redundancy

- In normal operation, power supply A and B share the load for maximum reliability.
- Power supply A supports the load if power supply B fails and vice versa.
- Blocking diodes protect the load from a faulty power supply affecting the load voltage.
- The load can be tens of amps.
- Dissipation in the diodes can be high!
- The ZXGD3102 is designed to switch the low on-resistance MOSFETs used to replace the blocking diodes.

Should Customers purchase or use Diodes Incorporated products for any unintended or unauthorized application, Customers shall indemnify and hold Diodes Incorporated and its representatives harmless against all claims, damages, expenses, and attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized application.

Products described herein may be covered by one or more United States, international or foreign patents pending. Product names and markings noted herein may also be covered by one or more United States, international or foreign trademarks.

LIFE SUPPORT

Diodes Incorporated products are specifically not authorized for use as critical components in life support devices or systems without the express written approval of the Chief Executive Officer of Diodes Incorporated. As used herein:

A. Life support devices or systems are devices or systems which:

1. are intended to implant into the body, or
2. support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in significant injury to the user.

B. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or to affect its safety or effectiveness.

Customers represent that they have all necessary expertise in the safety and regulatory ramifications of their life support devices or systems, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of Diodes Incorporated products in such safety-critical, life support devices or systems, notwithstanding any devices- or systems-related information or support that may be provided by Diodes Incorporated. Further, Customers must fully indemnify Diodes Incorporated and its representatives against any damages arising out of the use of Diodes Incorporated products in such safety-critical, life support devices or systems.
