4.5 V to 60 V Input, 6 A Synchronous Buck Regulator

DESCRIPTION

The SiC462 is a synchronous buck regulator with integrated high-side and low-side power MOSFETs. Its power stage is capable of supplying 6 A continuous current at up to 1 MHz switching frequency. This regulator produces an adjustable output voltage down to 0.8 V from 4.5 V to 60 V input rail to accommodate a variety of applications, including computing, consumer electronics, telecom, and industrial.

SiC462's architecture delivers ultra-fast transient response with minimum output capacitance and tight ripple regulation at very light load. The device is stable with any capacitor and no external ESR network is required for loop stability. The device also incorporates a power saving scheme that significantly increases light load efficiency.

The regulators integrates a full protection feature set, including output overvoltage protection (OVP), output undervoltage protection (UVP) and thermal shutdown (OTP). It also has UVLO for input rail and a user programmable soft start.

The SiC462 is available in lead (Pb)-free power enhanced MLP55-27L package.

FEATURES

- Single supply operation from 4.5 V to 60 V input voltage
- Adjustable output voltage down to 0.8 V
- 6 A continuous output current
- Selectable switching frequency from 100 kHz to 1 MHz with an external resistor
- 95 % peak efficiency
- Ultra-fast transient response
- Optional power saving mode
- < 10 µA shutdown current
- < 250 µA operating current when enabled but not switching
- Cycle-by-cycle current limit
- Output overvoltage protection
- Output undervoltage protection
- Output voltage tracking and sequencing
- -40 °C to +125 °C operating junction temperature

APPLICATIONS

- POLs for telecom
- Industrial and automation
- Industrial computing
- Consumer electronics

TYPICAL APPLICATION CIRCUIT AND PACKAGE OPTIONS

PIN CONFIGURATION

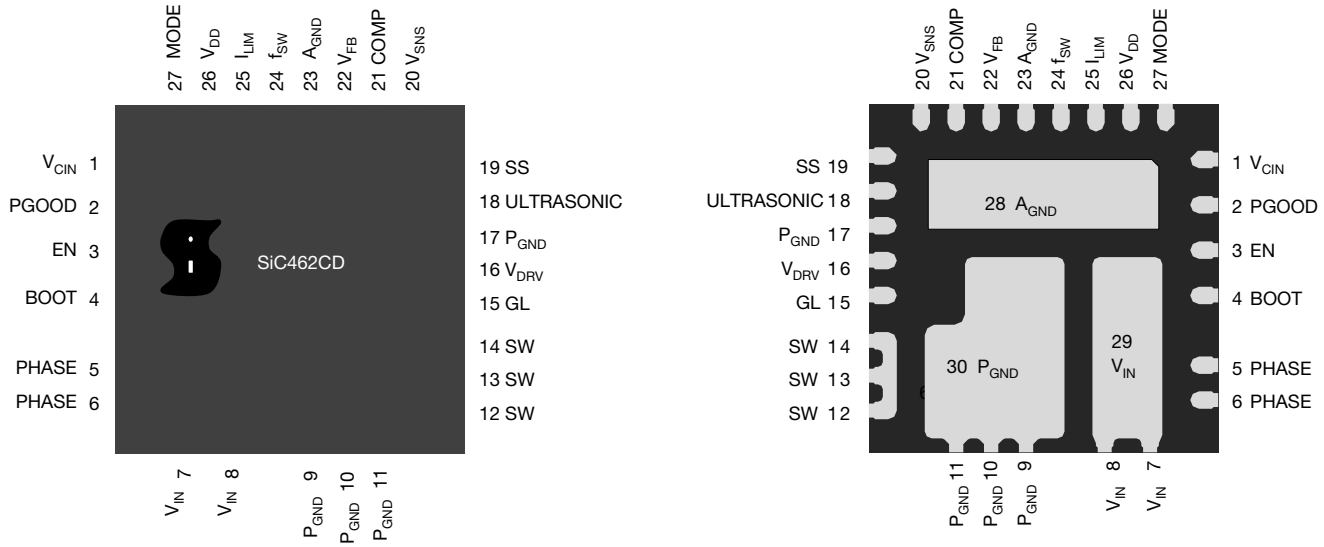

Fig. 2 - SiC462 Pin Configuration

PIN DESCRIPTION		
PIN NUMBER	**SYMBOL**	**DESCRIPTION**
1	V_{CIN}	Supply voltage for internal logic circuitry
2	PGOOD	Open-drain power good indicator - high impedance indicates power is good. An external pull-up resistor is required
3	EN	Enable pin
4	BOOT	High-side driver bootstrap voltage
5, 6	PHASE	Return path of high-side gate driver
7, 8, 29	V_{IN}	Power stage input voltage. Drain of high-side MOSFET
9, 10, 11, 17, 30	P_{GND}	Power ground
12, 13, 14	SW	Power stage switch node
15	GL	Low-side MOSFET gate signal
16	V_{DRV}	Supply voltage for internal gate driver. When using the internal LDO as a bias power supply, V_{DD} is the LDO output. Connect a 1 µF decoupling capacitor to A_{GND}
18	ULTRASONIC	Float to disable ultrasonic mode, connect to V_{DD} to enable. Depending on the operation mode set by the MODE pin, power save mode or forced continuous mode will be enabled when the ultrasonic mode is disabled
19	SS	Set the soft start ramp by connecting a capacitor to A_{GND}. An internal current source will charge the capacitor
20	V_{SNS}	Power inductor signal feedback pin for system stability compensation
21	COMP	Output of the internal error amplifier. The feedback loop compensation network is connected from this pin to the V_{FB} pin
22	V_{FB}	Feedback input for switching regulator used to program the output voltage - connect to an external resistor divider from V_{OUT} to A_{GND}
23	A_{GND}	Analog ground
24	f_{SW}	Set the on-time by connecting a resistor to A_{GND}
25	I_{LIMIT}	Set the current limit by connecting a resistor to A_{GND}
26	V_{DD}	Bias supply for the IC. V_{DD} is an LDO output, connect a 1 µF decoupling capacitor to A_{GND}
27	MODE	Use MODE to set various operation modes. See specification table

MODE4		Skip mode enabled, V_{DRV} Pre-reg off, V_{DD} Pre-reg on, provide external V_{DRV}	3.3	-	V_{DD}	

FUNCTIONAL BLOCK DIAGRAM

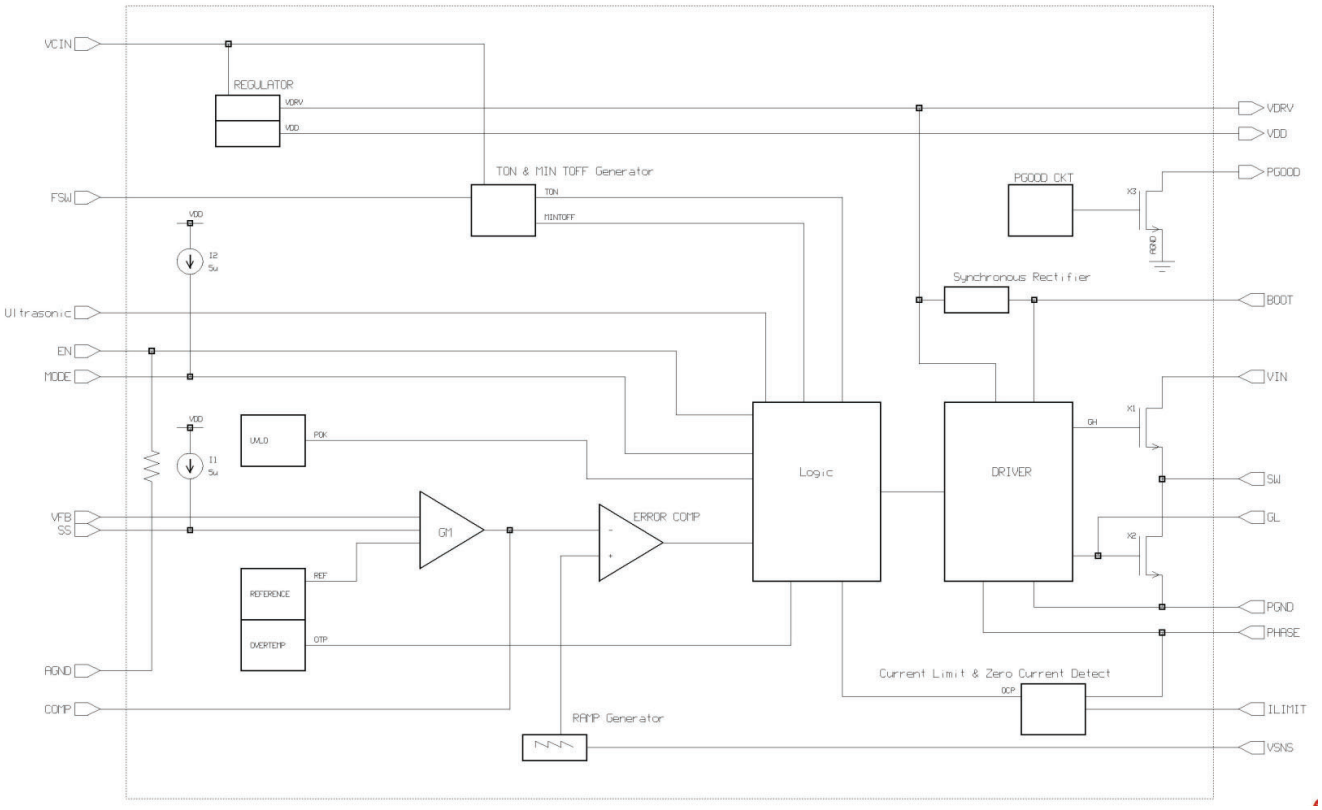

Fig. 3 - SiC462 Functional Block Diagram

OPERATIONAL DESCRIPTION

Device Overview

SiC462 is a high-efficiency synchronous buck regulator capable of delivering up to 6 A continuous current. The device has programmable switching frequency of 100 kHz to 1 MHz. The control scheme delivers fast transient response and minimizes external components. A proprietary V^2-COT control mechanism enables loop stability regardless of the type of output capacitor used, including low-ESR ceramic capacitors. This device also incorporates a power saving feature by enabling diode emulation mode and frequency fold back as the load decreases.

SiC462 has a full set of protection and monitoring features:

- Over current protection in pulse-by-pulse mode
- Output overvoltage protection
- Output undervoltage protection with device latch
- Over temperature protection with hysteresis
- Dedicated enable pin for easy power sequencing
- Power good open drain output
- This device is available in MLP55-32L package to deliver high power density and minimize PCB area.

Power Stage

SiC462 integrates a high-performance power stage with a 25 mΩ n-channel high side MOSFET and a 12 mΩ n-channel low side MOSFET. The MOSFETs are optimized to achieve up to 96 % efficiency.

The power input voltage (V_{IN}) can go up to 60 V and down as low as 5 V for power conversion.

PWM Control Mechanism

SiC462 employs a voltage - mode COT control mechanism with two voltage (V^2) feedback loops. The switching frequency, f_{SW}, it set by an external resistor to A_{GND}, R_{fsw}.

$$R_{fsw} = \frac{V_{OUT}}{(f_{SW} \times 190e^{-12})}$$

During steady-state operation, feedback voltage is compared with internal reference (0.8 V typ.) and the amplified error signal (V_{COMP}) is generated in the internal comp node. An internally generated ramp signal and V_{COMP} are fed into a comparator. Once V_{RAMP} crosses V_{COMP}, a single shot ON-time pulse is generated for a fixed time, programmed by the external R_{FSW}. During the On-time pulse, the high side MOSFET will be turned ON. Once the ON-time pulse expires, the low side MOSFET will be turned ON after a break-before-make period. The low side MOSFET will be on for duration of minimum OFF-time pulse until V_{RAMP} crosses V_{COMP}. The cycle is then repeated.

Fig. 4 illustrates the basic block diagram for V^2-COT architecture. In this architecture the following is achieved:

- The reference of a basic ripple control regulator is replaced with a high again error amplifier loop
- This establishes two parallel voltage regulating feedback paths, a fast and slow path (hence the term V^2 to indicate two voltage feedback paths)
- The fast path is the ripple injection which ensures rapid correction of the transient perturbation
- The slow path is the error amplifier loop which ensures the DC component of the output voltage follows the internal accurate reference voltage

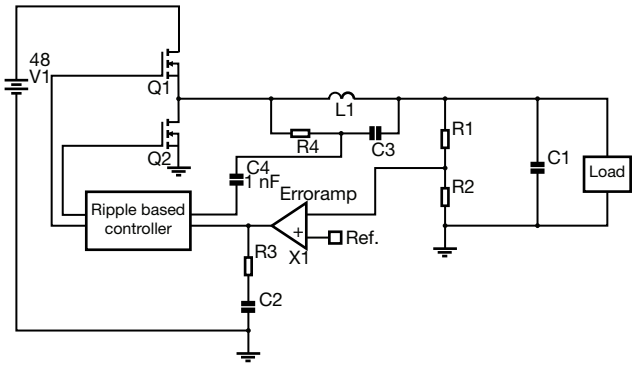

Fig. 4 - V^2-COT Block Diagram

For stability purposes the SiC462 requires 100 mV of ripple injection. C_X, C_Y, and R_X are selected to achieve the desired ripple injection.

Typically C_y is chosen to be ≥ 2 nF to meet the internal impedance of the V_{SNS} pin.

C_X is chosen to be 10 times greater than C_Y, C_Y = 20 nF.

$$R_X = (V_{IN} - V_{OUT}) \times (V_{OUT}/(V_{IN} \times f_{SW} \times C_X \times V_{RIPPLE}))$$

Fig. 5 demonstrates the basic operational waveforms:

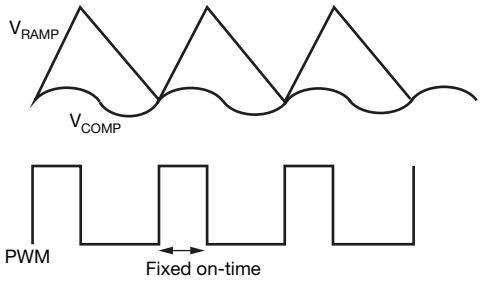

Fig. 5 - V^2-COT Operational Principle

Typically, the set the frequency of R_{COMP} and C_{COMP} is chosen to be around the resonance frequency of L_{OUT} and C_{OUT}.

In this case, set

$$R_{COMP} \times C_{COMP} = \sqrt{L_{OUT} \times C_{OUT}}$$

For good slew rate / transient load response, pick C_{COMP} ≤ 1 nF, R_{COMP} can be calculated according the formula above.

Power-Save Mode, MODE Pin, and Ultrasonic Pin Operation

To improve efficiency at light-load condition, SiC462 provides a set of innovative implementations to eliminate LS re-circulating current and switching losses. The internal zero crossing detector (ZCD) monitors LX node voltage to determine when inductor current starts to flow negatively. In power saving mode, as soon as inductor valley current crosses zero, the device first deploys diode emulation mode by turning off LS FET. If load further decreases, switching frequency is further reduced proportional to load condition to save switching losses while keeping output ripple within tolerance. The switching frequency is set by the controller to maintain regulation. If the ultrasonic pin is tied to V_{DD}, the minimum switching frequency that the regulator will drop to, as load decreases, is 20 kHz to avoid switching frequencies in the audible range. If this feature is not required this ultrasonic mode can be disabled by floating the ultrasonic pin. When the ultrasonic mode is disabled, the regulator will either operate in forced continuous mode or in a power save mode where there is no limit to the lower frequency limit. In this state, at zero load switching frequency can go as low as hundreds of Hz.

If a 5 V rail is available in the system, the customer can provide this as the V_{DRV} voltage instead of using the internal V_{DRV} regulator. This allows for power savings because power is not dissipated in the internal regulator.

The MODE pin supports several modes of operation as shown below. An internal current source is used to set the voltage on this pin using an external resistor:

TABLE 1 - OPERATION MODES	
MODE1 0 V to 0.7 V	Power save mode enabled, V_{DD},V_{DRV} Pre-reg on
MODE2 1.3 V to 1.7 V	Power save mode disabled, V_{DD}, V_{DRV} Pre-reg on
MODE3 2.3 V to 2.7 V	Power save mode disabled, V_{DRV} Pre-reg off, V_{DD} Pre-reg on, provide external V_{DRV}
MODE4 3.3 V to V_{DD}	Power save mode enabled, V_{DRV} Pre-reg off, V_{DD} Pre-reg On, provide external V_{DRV}

The mode pin is not latched to any state and can be changed on the fly.

OUTPUT MONITORING AND PROTECTION FEATURES

Output Over-Current Protection (OCP)

SiC462 has cycle by cycle current limiting. The inductor valley current is monitored during LS FET turn-on period through $R_{DS(on)}$ sensing. After a pre-defined blanking time, the valley current is compared with an internal threshold. If monitored current is higher than threshold, HS turn-on pulse is skipped and LS FET is kept on until the valley current returns below OCP limit.

In the severe over-current condition, cycle by cycle current limit eventually triggers output undervoltage protection (UVP) and the device will go into hiccup mode as described in the next section.

OCP is enabled immediately after V_{CC} passes UVLO level.

OCP is set by an external resistor to A_{GND}, R_{LIM}.

$$R_{LM} = 480k / I_{OUT\ max.}$$

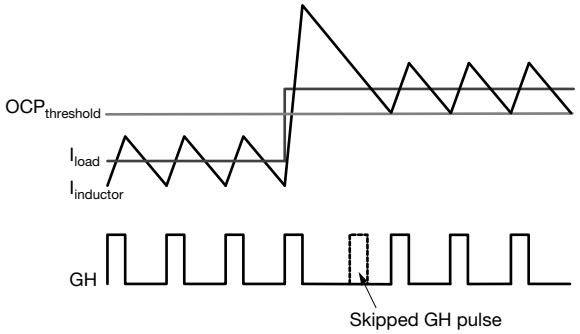

Fig. 6 - Over-Current Protection Illustration

Output Undervoltage Protection (UVP)

UVP is implemented by monitoring output through V_{FB} pin. If the voltage level at V_{FB} goes below 0.16 V (V_{OUT} is 20% of V_{OUT} set point) for more than 25 µs, then a UVP event is recognized and both HS and LS MOSFETs are turned off. After a period of 20 soft start cycles, the IC attempts to re-start and goes through a soft start cycle. If the fault condition still exists, the above cycle will be repeated.

UVP is only active after the completion of soft-start sequence.

Output Over-Voltage Protection (OVP)

For OVP implementation, output is monitored through FB pin. After soft start, if the voltage level at FB is above 0.96 V (typ.) (V_{OUT} is 120 % of V_{OUT} set point), OVP is triggered with both the HS and LS MOSFETs turned off. Normal operation is resumed once FB voltage drops back to 0.96 V.

OVP is active immediately after V_{CC} passes UVLO level.

Over-Temperature Protection (OTP)

SiC462 has internal thermal monitor block that turns off both HS and LS FETs when junction temperature is above 150 °C (typ). A hysteresis of 35 °C is implemented, so when junction temperature drops below 115 °C, the device restarts by initiating soft-start sequence again.

Sequencing of Input / Output Supplies

SiC462 has no sequencing requirements on any of its input/output (V_{IN}, V_{DRV}, V_{DD}, V_{CIN}, EN) supplies or enables.

Enable

The SiC462 has an enable pin to turn the part on and off. Driving this pin high enables the device, while grounding it turns it off.

The SiC462 enable has a weak pull down to prevent unwanted turn on due to a floating GPIO.

There are no sequencing requirements w.r.t other input/output supplies.

Soft-Start

SiC462 soft-start time is adjustable by selecting a capacitor value from the following equation. Once V_{CC} is above UVLO level (2.55 V typ.), V_{OUT} will ramp up slowly, rising monotonically to the programmed output voltage. There is an internal 5 µA current source tied to the soft start pin which charges the external soft start cap.

$$\text{SS time} = \frac{C_{ext} \times 0.8\ V}{5\ \mu A}$$

During soft-start period, OCP is activated. Short-circuit protection is not active until soft-start is complete.

Pre-Bias Start-Up

In case of pre-bias startup, output is monitored through FB pin. If the sensed voltage on FB is higher than the internal reference ramp value, control logic prevents HS and LS FET from switching to avoid negative output voltage spike and excessive current sinking through LS FET.

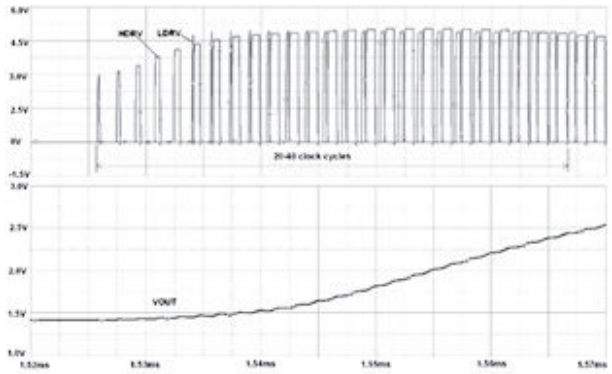

Fig. 7 - Pre-bias Start-up

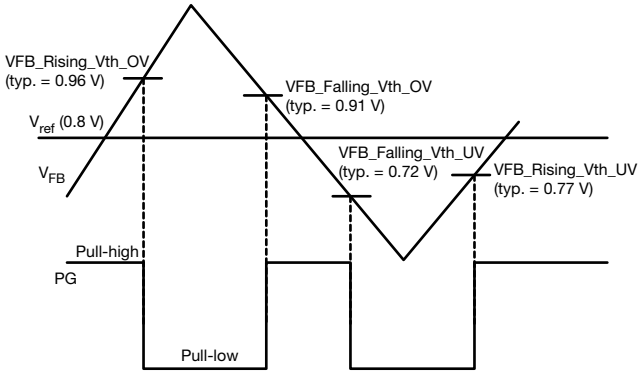

Fig. 8 - PGOOD Window and Timing Diagram

Power Good

SiC462's power good is an open-drain output. Pull PGOOD pin high up to 5 V through a 10K resistor to use this signal. Power good window is shown in the diagram above. If voltage level on FB pin is out of this window, PG signal is de-asserted by pulling down to GND. To prevent false triggering during transient events, PGOOD has a 25 µs blanking time.

EXTERNAL COMPONENT SELECTION FOR THE SiC462

A reference design has been developed to illustrate how to choose component values for proper operation of the SiC462. The schematic for the demo board is shown in Fig. 9 and Table 2.

Demo Board Connection and Signal / Test Points

Power Sockets

V_{IN}, GND (P1): input voltage source with V_{IN} to be positive. Connect to a voltage source:

V_{OUT}, GND (P3): output voltage with V_{OUT} to be positive. Connect to a load that draws no more than:

5 V, GND (P10): external 5 V MOSFET gate voltage source with 5 V to be the positive input. Apply 5 V when Mode 3 or Mode 4 is selected.

Selection Jumpers

Mode Select

P7: this is an 8 way header which allows the user to select one of four modes of operation.

MODE1 - SHORT PIN 1 to 2 Power save, V_{DRV} and Pre-reg on

MODE2 - SHORT PIN 3 to 4 Forced PWM, V_{DRV} and Pre-reg on

MODE3 - SHORT PIN 5 to 6 Forced PWM, V_{DRV} and Pre-reg off - external 5 V supply

MODE4 - SHORT PIN 7 to 8 Power save, V_{DRV} and Pre-reg off - external 5 V supply

V_{DRV} External Supply

P10: this is a 2 way header that will enable the user to supply an external MOSFET gate driver supply if an external 5 V supply is available. This should only be used in MODES 3 and 4.

ENABLE

P9: this is a 2 way header that will enable the part if left open. When shorted the part is disabled.

OPEN Pin 1-2 - automatic enable on power up
SHORT Pin 1-2 - IC disabled.

Ultrasonic

P8: this is a 2 way header that will enable the user to select the ultrasonic mode of operation. In ultrasonic mode the minimum frequency of operation is 20 kHz, above the audible range. When not in ultrasonic mode the frequency can drop below 20 kHz.

OPEN Pin 1-2 - ultrasonic disabled
SHORT Pin 1-2 - ultrasonic enabled

SIGNALS AND TEST LEADS

Input Voltage Sense

V_{IN_SENSE}, GND_{IN_SENSE} (P2): this allows the user to measure the voltage at the input of the regulator and remove any losses generated due to the, connections from the measurement. This can also be used by a power source with sense capability.

Output Voltage Sense

V_{OUT_SENSE}, GND_{OUT_SENSE} (P4): this allows the user to measure the voltage at the output of the regulator and remove any losses generated due to the connections, from the measurement. This can also be used by an active load with sense capability.

POWER GOOD INDICATOR

PGOOD (P11): is an open drain output and is pulled up with a 10 kΩ resistor to V_{IN}. When FB or V_{OUT} are within -10 % to +20 % of the set voltage this pin will go HI to indicate the output is okay.

POWER UP PROCEDURE

To turn-on the reference board, apply 12 V to V_{IN} with the P7 jumper is in position 1. If the P7 jumper is in place 1 the board will come up in power save mode, if in place 2 then constant PWM will be observed.
When applying higher than 12 V to the input it is reasonable to install a RC snubber from LX to GND if needed however this will affect efficiency. There are place holders on the reference board, R11 and C12 for the snubber. Values of 4 Ω and 1 nF are a reasonable starting point.

ADJUSTMENTS TO THE REFERENCE BOARD

OUTPUT VOLTAGE ADJUSTMENT

If a different output voltage is needed, simply change the value of V_{OUT} and solve for R12 based on the following formula:

$$R_{12} = \frac{R_{13}(V_{OUT} - V_{FB})}{V_{FB}}$$

Where V_{FB} is 0.8 V for the SiC46X. R_{BOTTOM} (R13) should be a maximum of 10 kΩ to prevent V_{OUT} from drifting at no load.

CHANGING SWITCHING FREQUENCY

The following equation illustrates the relationship between on-time, V_{IN}, V_{OUT}, and R_{fsw} value:

$$R_{fsw} = R_7 = \frac{V_{OUT}}{f_{sw} \times 190e^{-12}}$$

OUTPUT RIPPLE VOLTAGE

There is no requirement for this converter to see output capacitor ripple voltage in the control loop as a voltage injection circuit is employed; the voltage injection ramp is used to alert the converter to the next switch event.

Output ripple voltage is measured with a tip and barrel measurement across C_{OUT}; the barrel of the probe is the GND / 0 V connection and this removes the effect of the long

GND / 0 V leads of the probe. Typically output ripple voltage is set to 3 % to 5 % of the output voltage, but an all ceramic output solution can bring output ripple voltage to a much lower level since the ESR of ceramics can be in the range of mΩ's.

VOLTAGE INJECTION NETWORK

This is the network seen placed across the output inductor in the schematic consisting of R10, C10 and C11. A quick method to add or remove injection is to reduce or increase R10.

The time constant of the inductor, τIND, and voltage injection network are as follows:

$$\tau_{IND} = \frac{L}{DCR}$$

and

$$\tau_{INJ} = R_L \times C_L$$

In order to set a correct magnitude, the SiC46x requires around 100 mV, the following equation is used:

$$R_L = (V_{IN} - V_{OUT}) \times \left(\frac{V_{OUT}}{V_{OUT} \times f_{sw} \times C_L \times V_{INJECTION}} \right)$$

Where $V_{INJECTION}$ = 100mV is the midpoint of the ripple injection RC circuit.

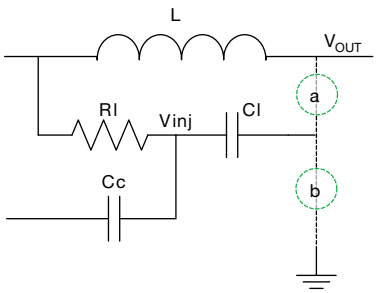

Fig. 9 - Voltage Injection Circuit

In fig. 1 the recommended value of CI = C10 (a or b) ≈ 2.2 nF and Cc = C11 ≈ 22 nF.

The reference design allows placement of CI in two positions as shown in fig. 1, “a” and “b”. The “b” option removes the output ripple and transient response voltage from the injection signal. The effect of connecting the CI capacitor to GND / 0 V is that some of the output information is removed from the fast loop however the output will be very stable in this setup when large transient loads are experienced at the output; in any case you will notice that the effective impedance of the output node is very small and the FB loop will react quickly enough for all loads. Another key aspect of using the GND / 0 V connection for the injection circuit is the ability to use a smaller output capacitance.

Be aware that the b) option is should only be used with forced PWM operation.

$$V_{INJ} = (V_{IN\_min.} - V_{OUT}) \times \left(1 - \frac{1}{e^{\frac{t}{\tau_{IN}}}} \right)$$

Where t is the ON period. The required magnitude is ~ 100 mVpp for stable operation.

Compensation

The COT loop uses a transconductance amplifier to convert a proportional current from the output voltage, V_{FB}. This has the effect of offering a high impedance at the V_{FB} node, however this circuitry is left with a wide bandwidth to accommodate the different switching frequencies. This will require rolling off with an RC circuit, use the following equation:

$$R_{COMP} = \frac{\sqrt{L \times C_{OUT}}}{C_{COMP}}$$

C_{COMP} will be set to 1 nF. This provides a frequency breakpoint around the LC filter peak. It may be necessary to reduce the roll off further, this can be a choice of the designer but an example might be to start at 1/2 the LC filter peak frequency. This will affect the transient response time, something to note is the minimal phase delay in the COT topology and its fast response compared to PWM converters.

INDUCTOR SELECTION

The choice of inductor is specific to each application and quickly determined with the following equations:

$$t_{ON} = \frac{V_{OUT}}{V_{IN\_max.} \times f_{sw}}$$

and

$$L = \frac{(V_{IN} - V_{OUT}) \times t_{ON}}{I_{OUT\_max.} \times K}$$

Where K is a percentage of maximum output current ripple required. The designer can quickly make a choice of inductor if the ripple percentage is decided, usually no more than 30 % however higher or lower percentages of I_{OUT} can be acceptable depending on application. This device allows choices larger than 30 %.

Other than the inductance the DCR and saturation current parameters are key values. The DCR causes an I^2R loss which will decrease the system efficiency and generate heat. The saturation current has to be higher than the maximum output current plus ½ of the ripple current. In an over current condition the inductor current may be very high. All this needs to be considered when selecting the inductor.

On this board Vishay IHLP series inductors are used to meet cost requirement and high efficiency, a part that utilizes a material that has incredible saturation behaviour compared to competing products.

OUTPUT CAPACITOR SELECTION

Voltage rating, ESR, transient response, overall PCB area and cost are requirements for selecting output capacitors. The types of capacitors and there general advantages and disadvantages are covered next.

Electrolytic have high ESR, dry out over time so ripple current rating must be examined and have slower transient response, but are fairly inexpensive for the amount of overall capacitance.
Tantalums can come in low ESR varieties and high capacitance value for its overall size, but they fail short when damaged and also have slower transient response.

Ceramics have very low ESR, fast transient response and overall small size, but come in low capacitance values compared to the others types. A combination of technology is sensible, however these converters suit an ceramic solution also.

The output capacitance will be determined by the ripple voltage requirement. Voltage mode COT topology can work with very small values of capacitor ESR.

The following equations are used to calculate the size needed to meet a transient load response:

$$I_{LPK} = I_{max.} + 0.5 \times I_{RIPPLE\_max.}$$

and

$$C_{OUT\_min.} = I_{LPK} \times \frac{L \times \frac{I_{LPK}}{V_{OUT}} - \frac{I_{max.}}{dI_{LOAD}} \times dt}{2 \times (V_{PK} - V_{OUT})}$$

Where I_{LPK} is the peak inductor current, $I_{MAX.}$ is the maximum output current, dI_{LOAD} is the current step in µs and V_{PK} is the peak voltage, the output voltage summed with the specified over and under shoot.

The evaluation PCB is fitter with 66 µF.

ENABLE PIN VOLTAGE

The EN pin has an internal pull down resistor and only requires an enable voltage. This needs to be greater than 1.4 V. An input voltage or a resistor connected across V_{IN} and EN can be used. The internal pull down resistance is 5 MΩ.

SOFT START SETTING

Soft start is a useful function helping to limit the current magnitude from the source at switch on. This is simply set with a ceramic capacitor using the following equation:

$$t_{SS} = \frac{C_{SS} \times 0.8}{5e^{-6}}$$

A 100 nF capacitor will provide ~ 16 ms soft start time. V_{DD} pin will need to be decoupled in order to provide a stable voltage internally and externally. The value for this capacitor is recommended as ≥ 1 µF.

CURRENT LIMIT RESISTOR

The current limit is set by placing a resistor between pins LXS and I_{LIM}. The values can be found using the following equation:

$$R_{ILIM} = \frac{480\,000}{I_{OUT\_max.}}$$

INPUT CAPACITANCE

In order to keep the design compact and minimize parasitic elements, ceramic capacitors will be chosen. The initial requirement for the input capacitance is decided by the maximum input voltage, 60 V in this case however a 100 V rated capacitor will be chosen of the X7R variety. The footprint will be a compact 1206.

In order to determine the minimum capacitance the input voltage ripple needs to be specified; $V_{CINPP} \leq 500$ mV is a suitable starting point. This magnitude is determined by the final application specification. The input current needs to be determined for the lowest operating input voltage,

$$I_{CIN(RMS)} = \frac{I_{OUT}}{V_{IN}} \times \sqrt{V_{OUT} \times (V_{IN} - V_{OUT})}$$

The minimum input capacitance can then be found,

$$C_{IN\_min.} = I_{OUT} \times \frac{DC - (1 - DC)}{V_{CINPKPK} \times f_{sw}}$$

For output voltage greater than 5 V the input capacitance should be increased accordingly. As the output power increases so does the input voltage ripple, the evaluation PCB has 4.4 µF.

Note

- If the input voltage becomes very small then extra capacitance needs adding to the input as the ripple will affect the duty cycle calculation when larger current is required.

ELECTRICAL CHARACTERISTICS (V_{IN} = 48 V, V_{OUT} = 5 V, f_{sw} = 300 kHz, L = 15 µH, unless noted otherwise)

PCB LAYOUT RECOMMENDATIONS

Step 1: V_{IN}/GND Planes and Decoupling

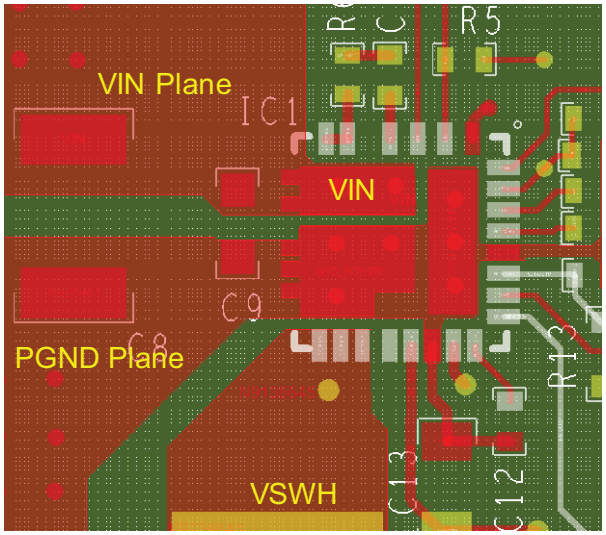

Fig. 28

1. Layout V_{IN} and P_{GND} planes as shown above.
2. Ceramic capacitors should be placed between V_{IN} and P_{GND}, and very close to the device for best decoupling effect.
3. Different values / packages of ceramic capacitors should be used to cover entire decoupling spectrum e.g. 1210 and 0603.
4. Smaller capacitance values, placed closer to device's V_{IN} pin(s), is better for high frequency noise absorbing.

Step 2: V_{CIN} Pin

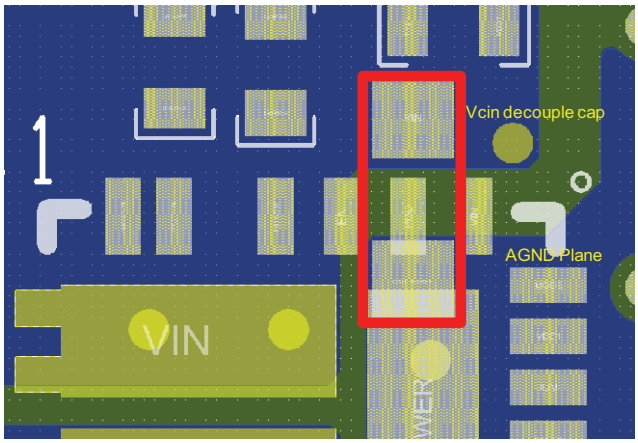

Fig. 29

1. V_{CIN} (pin 1) is the input pin for both internal LDO and t_{ON} block. T_{ON} time varies based on input voltage. It's necessary to put a decoupling capacitor close to this pin.
2. The connection can be made through a via and the cap can be placed at bottom layer.

Step 3: V_{SWH} Plane

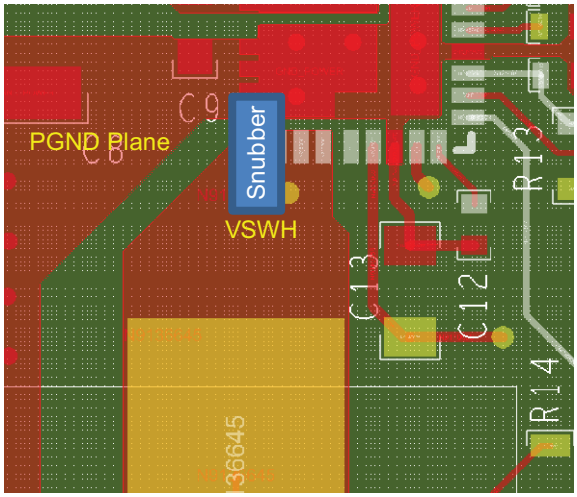

Fig. 30

1. Connect output inductor to SiC462 with large plane to lower the resistance.
2. If any snubber network is required, place the components on the bottom side as shown above.

Step 4: V_{DD}/V_{DRV} Input Filter

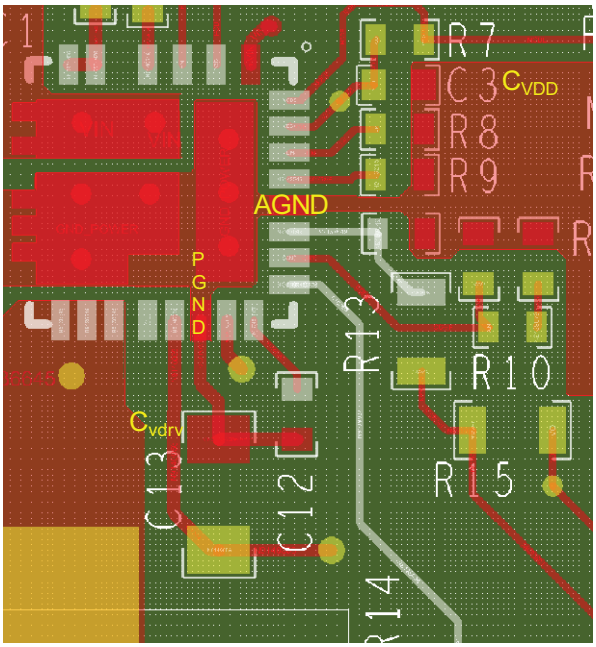

Fig. 31

1. C_{VDD} cap should be placed between pin 26 and pin 23 (the A_{GND} of driver IC) to achieve best noise filtering.
2. C_{VDRV} cap should be placed close to V_{DRV} (pin 16) and P_{GND} (pin 17) to reduce effects of trace impedance and provide maximum instantaneous driver current for low side MOSFET during switching cycle.

Step 5: BOOT Resistor and Capacitor Placement

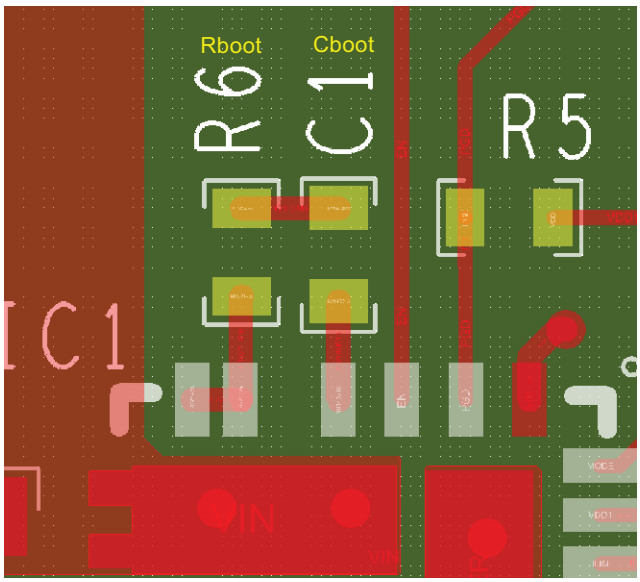

Fig. 32

1. These components need to be placed very close to SiC462, right between PHASE (pin 5, 6) and BOOT (pin 4).
2. In order to reduce parasitic inductance, it is recommended to use 0402 chip size for the resistor and the capacitor.

Step 6: Signal Routing

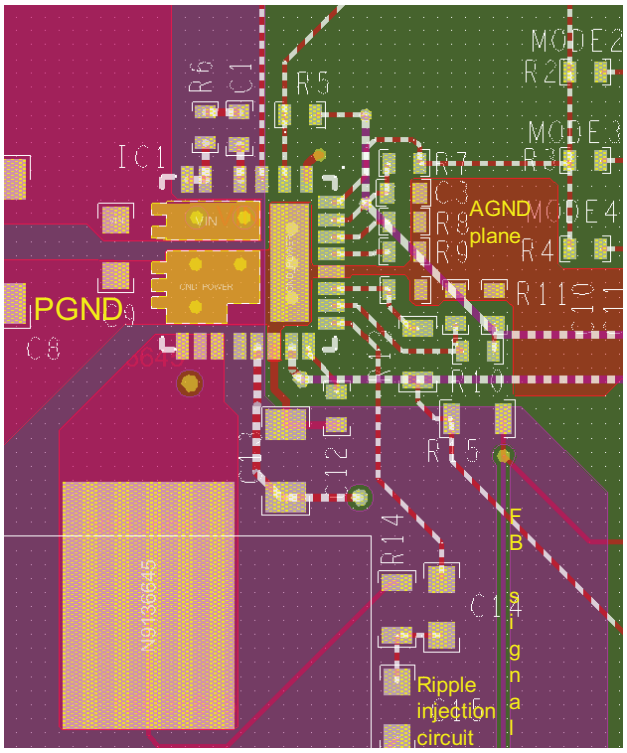

Fig. 33

1. Separate the small analog signal from high current path. As shown above, the high current paths with high dv/dt, di/dt are placed on the left side of the IC, while the small control signals are placed on the right side of the IC. All the components for small analog signal should be placed closer to IC with minimum trace length.
2. Pin 23 is the IC analog ground, which should have a single connection to power ground. The A_{GND} ground plane connected with pin 23 helps keep A_{GND} quiet and improve noise immunity.
3. Feedback signal can be routed through inner layer. Make sure this signal is far away from V_{SWH} node and shielded by inner ground layer.
4. Ripple injection circuit can be placed next to inductor. Kelvin connection as shown above is recommended.

Step 7: Adding Thermal Relief Vias and duplicate Power Path Plane

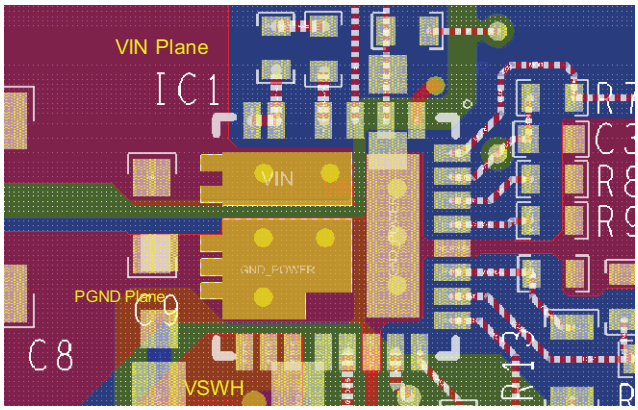

Fig. 34

1. Thermal relief vias can be added on the V_{IN} and P_{GND} pads to utilize inner layers for high-current and thermal dissipation.
2. To achieve better thermal performance, additional vias can be put on V_{IN} and P_{GND} plane. Also, it is necessary to duplicate the V_{IN} and ground planes at bottom layer to maximize the power dissipation capability from PCB.
3. V_{SWH} pad is a noise source and not recommended to put vias on this pad.
4. 8 mil drill for pads and 10 mils drill for plane are optional via sizes. The vias on pads may drain solder during assembly and cause assembly issues. Please consult with the assembly house for guidelines.

Step 8: Ground Layer

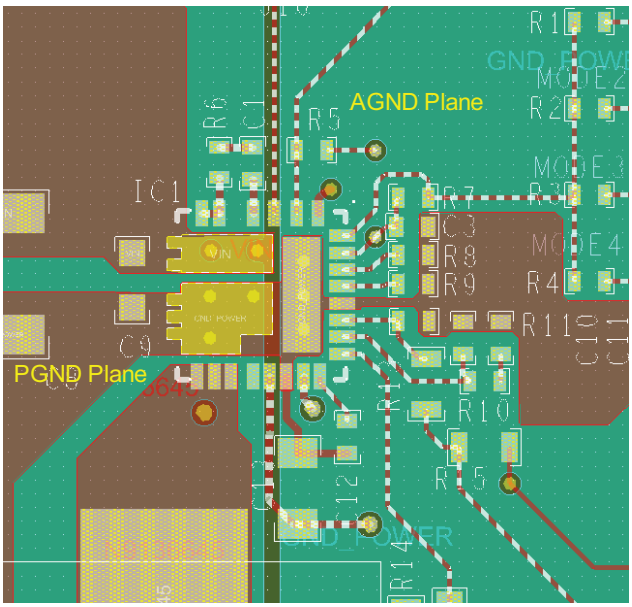

Fig. 35

1. It is recommended to make the entire inner layer (next to top layer) ground plane.
2. This ground plane provides shielding between noise source on top layer and signal trace within inner layer.
3. The ground plane can be broken into two sections as P_{GND} and A_{GND}.

Notes

1. Use millimeters as primary measurement
2. Dimensioning and tolerances conform to ASME Y14.5M - 1994
3. N is the number of terminals, Nd is the number of terminals in x-direction, and Ne is the number of terminals in y-direction
4. Dimension b applies to plated terminal and is measured between 0.20 mm and 0.25 mm from terminal tip
5. The pin #1 identifier must be existed on the top surface of the package by using indentation mark or other feature of package body
6. Exact shape and size of this feature is optional
7. Package warpage max. 0.08 mm
8. Applied only for terminals

Vishay Siliconix maintains worldwide manufacturing capability. Products may be manufactured at one of several qualified locations. Reliability data for Silicon Technology and Package Reliability represent a composite of all qualified locations.
